**Abstract:** The recently discovered [4+1]-spirocyclization of nitroalkenes to indoles provided a convenient new approach to 2-(1*H*-indol-2-yl)acetonitriles. However, this reaction was complicated by the formation of inert 3-(2-nitroethyl)-1*H*-indole byproducts. Herein, we offer a workaround this problem that allows for effective transformation of the unwanted byproducts into acetonitrile target molecules.

## 1. Introduction

Derivatives of 1*H*-indole-2-acetic acid are common, naturally occurring indoline alkaloids with important bioactivities [1–10]. These compounds were used as key intermediates in total syntheses of several natural products and nonnatural pharmaceutical agents [11–17]. Thus, synthetic methods for selective preparation of these 1*H*-indole derivatives remain the focus of many research groups. Recently, we reported an unusual, acid-assisted [4+1]-cycloaddition of indoles **1** with nitroalkenes **2** that provides 4'*H*-spiro[indole-3,5'-isoxazoles] **5** in a diastereomerically pure form (Scheme 1) [18,19]. It was confirmed that this spirocyclization occurs via nitronate intermediate **3**. This species, however, was susceptible to a facile isomerization into more thermodynamically stable nitroalkane **4**, which proved to be inert under the reaction conditions. It was also shown that spiroheterocycles **5** underwent a diastereoselective rearrangement to afford nitriles **6** (Scheme 1) [20]. A shortcut approach involving the formation of nitriles directly from **1** and **2** was also demonstrated. However, nitroalkanes **4** were unproductive in this reaction, which lowered the overall yield in this cascade transformation. Herein, we disclose a new method for an efficient activation of **4** toward spirocyclization, which allowed for a straightforward access to nitriles **6**. It should be noted that multiple methods for direct reductive conversion of nitroalkanes into nitriles have been reported [21–29]; however, the transformation described in this work is not mechanistically related to any of the known processes.

## 2. Results and Discussion

We have previously reported that generation of the key 4'*H*-spiro[indole-3,5'-isoxazole] 5 [18,19] takes place under acidic conditions, while isomerization of the latter into nitrile 6 occurs in the presence of weak bases [20]. Arguably, activation of nitroalkane 4 toward the desired transformation requires generation of nitronic acid 3 (also known as *aci*-form), which occurs in a basic medium [18]. To test this idea, nitroalkane **4ba** was refluxed in benzene in the presence of several carboxylic acids/triethylamine combinations (Table 1, entries 1,2). None of these trials enabled the desired reaction leaving starting material **4ba** intact. A stronger Bronsted acid, such as triflic acid, was also tested under these conditions but only led to rapid decomposition of the organic material.

<sup>a</sup> NMR yields are reported unless specified otherwise. The best result is shown in bold. <sup>b</sup> Isolated yield of purified product is provided.

At room temperature, however, traces of product **6ba** were detected by GC/MS (entry 3). It became evident from these experiments that nitronate species **3**, once generated, immediately tautomerized back into a more stable and inert nitroalkane **4**. We envisioned that this issue could potentially be addressed by *in situ* acylation of the nitronate. Accordingly, the acidic reagent was replaced with acetyl or benzoyl chloride, but both these tests resulted in no reaction (Table 1, entries 4,5). Phosphorus trichloride and trimethylphosphite were also probed, as they were previously shown to promote the spirocyclization step. However, both allowed for only trace amounts of **6ba** (entries 6,7). In contrast, thionyl chloride gave moderate to fair yields with most amine additives tested (entries 8–11). Encouraged by these results, we further explored an *in situ* phosphorylation of nitronate species with  $\text{POCl}_3$ . The use of two equivalents of  $\text{POCl}_3$  and excess triethylamine in boiling benzene gave rise to 53% yield of **6ba** (entry 12). Employment of a large excess  $\text{POCl}_3$  with 2.0 equiv. of base resulted in a notable yield reduction (entry 13). Finally, a reaction performed in benzene at room temperature afforded **6ba** as a sole isolable product (entry 14). This reaction was repeated in a preparative scale and, after isolation and purification, afforded the target nitrile in 72% yield. Further optimization attempts were unproductive and led to a decreased product yield (entries 15–20).

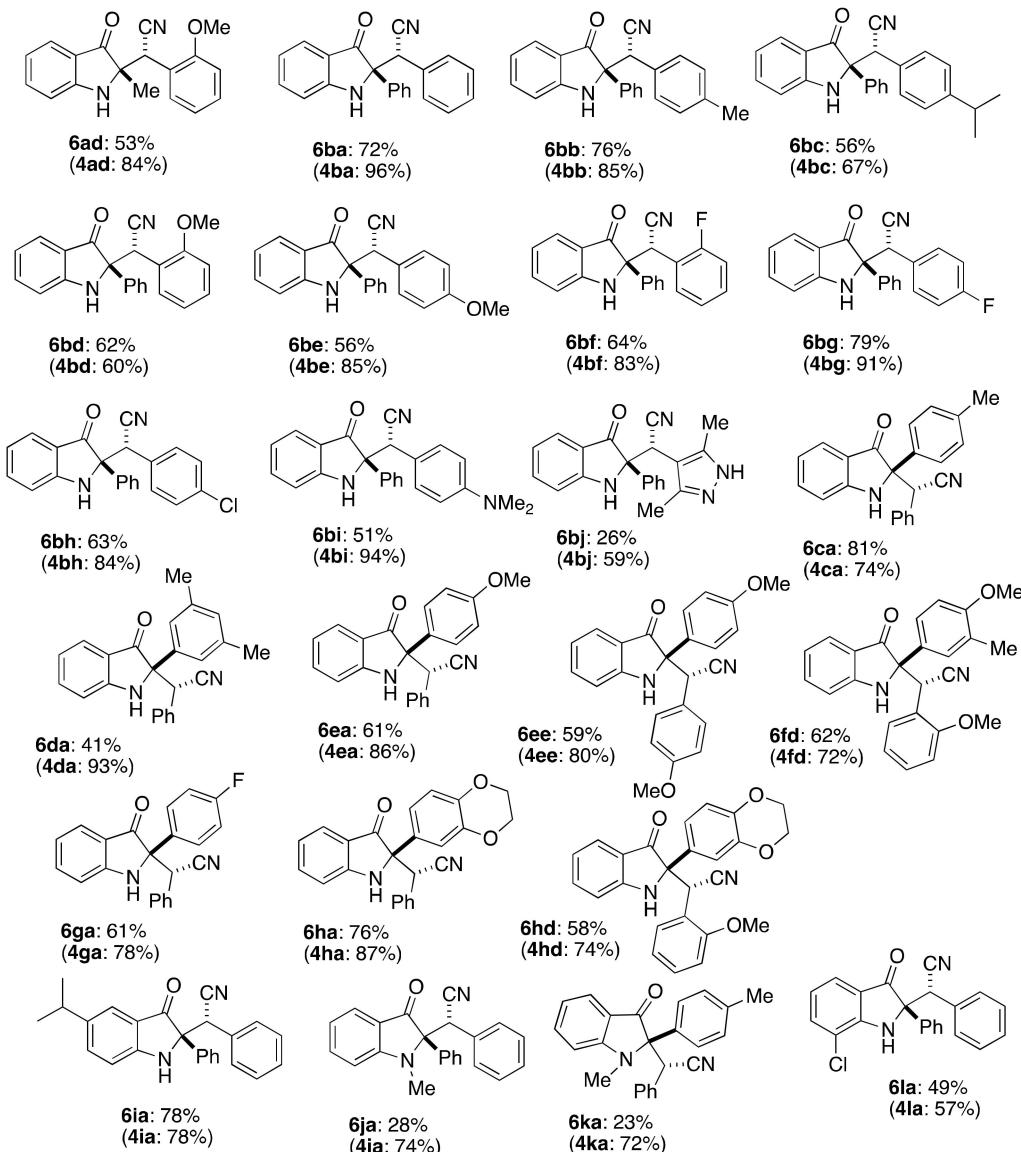

With optimized conditions in hand, we proceeded with synthesis of a small, focused library of analogs and also performed a scope and limitations studies. Starting nitroalkanes **4** were routinely prepared in high yields via electrophilic alkylation of indoles **1** with nitroalkenes **2** in boiling acetic acid. Isolated and purified **4** were then subjected to the reaction with  $\text{POCl}_3$  and  $\text{NEt}_3$  in benzene at room temperature. The results are summarized in Scheme 2. The standard reaction conditions afforded meaningful preparative yields across a large spectrum of substrates. Most substituents and functional groups tested (Alk, OAlk, Hal, NMe<sub>2</sub>) were well tolerated. Expectedly, lower yields were obtained for *N*-substituted indoles (**4ja**,**4ka**), because these reactions proceed via a less stable, charged *N*-methyliminium species **10** (Scheme 3 *vide infra*) [20]. Product **6bj** bearing a bulky and acid-sensitive 3,5-dimethyl-1*H*-pyrazolyl moiety was also formed in a notably lower yield (Scheme 2). The 2-(1*H*-indol-2-yl)acetonitrile core was unambiguously confirmed by a single crystal X-ray diffraction of product **6ia** (Figure 1).

A mechanistic rationale of the reported transformation is summarized in Scheme 3. Initially, a base-assisted tautomerization of nitroalkane **4** affords nitronic acid species **3**, which subsequently with phosphoryl chloride giving rise to phosphorylated nitronate **7**. Next, deprotonation at the adjacent carbon produces enamine species **8**. Subsequent elimination of the phosphoryl moiety affords oxime **9**, which, once formed, undergoes a 5-*endo-trig* cyclization to provide a spirocyclic iminium species **10**, which was described in our previous report [18] (Scheme 3). If  $R^3 = H$ , a deprotonation may occur, leading to a more stable imine form **5**, as shown in Scheme 1 (*vide supra*). Finally, a base-assisted ring cleavage [20] furnishes nitrile **6**. This transformation involves rearrangement **10** (also shown in Scheme 3 in aminocarbenium resonance form **11**) to afford dihydrooxazinium species **12**. Finally, deprotonation at C-3 accompanied by cleavage of the N-O bond furnished nitrile **6** (Scheme 3). It should be pointed out that the spirocyclic intermediate **5** was successfully isolated from a reaction of **4ba**, which was quenched at the early stage of product formation. When resubjected to the standard reaction conditions, isolated **5** provided nitrile **6ba** as a sole product in high yield.

### 3. Conclusions

An efficient protocol for activation of 3-(2-nitroethyl)-1*H*-indoles **4** toward spirocyclization and subsequent rearrangement into 2-(1*H*-indol-2-yl)acetonitriles **6** was developed. It was proposed that the activation mechanism involves stabilization of the reactive nitronate tautomeric species in the form of phosphorylated mixed anhydride **7** produced upon interaction of otherwise nonreactive nitroalkane **4** with phosphoryl chloride in the presence of base. This methodology was employed to synthesize a small, focused library of nitriles. Investigation of biological activity of these new 2-(1*H*-indol-2-yl)acetonitriles is currently under way in our laboratories.

NMR spectra  $^1\text{H}$  and  $^{13}\text{C}$  were measured in solutions of  $\text{CDCl}_3$  or  $\text{DMSO}-d_6$  on Bruker AVANCE-III HD instrument (at 400.40 or 100.61 MHz, respectively). HRMS spectra were measured in MeCN solutions on Bruker maXis impact (electrospray ionization, employing  $\text{HCO}_2\text{Na}-\text{HCO}_2\text{H}$  for calibration). See Supplementary Materials for NMR (S2–S97) and HRMS (S98–S114) spectral charts. IR spectra was measured on FT-IR spectrometer Shimadzu IRAffinity-1S equipped with an ATR sampling module. Reaction progress, purity of isolated compounds, and  $R_f$  values were assessed by TLC on Silufol UV-254 plates. Column chromatography was performed on silica gel (32–63  $\mu\text{m}$ , 60  $\text{\AA}$  pore size). Melting points were measured on Stuart SMP30 apparatus. All reagents and solvents were purchased from commercial vendors and used as received.

**Preparation of 3-(2-nitroethyl)-1*H*-indoles 4 (general procedure):** A 5-mL round-bottom flask was charged with indole **1** (2.0 mmol),  $\beta$ -nitrostyrene **2** (2.1 mmol), acetic acid (10  $\mu\text{L}$ ) and ethanol (1 mL). The mixture was refluxed for 2–8 h, while the reaction progress was monitored by TLC. After complete consumption of the starting material, the mixture was cooled down to room temperature, and the resulting precipitate was collected by filtration. Alternatively, the reaction mixture was concentrated in vacuo, and the residue was purified by preparative column chromatography (eluent  $\text{EtOAc}/\text{Hex}$  1:4).
