**Abstract:** In this critical review, plant sources used as effective antibacterial agents against *Helicobacter pylori* infections are carefully described. The main intrinsic bioactive molecules, responsible for the observed effects are also underlined and their corresponding modes of action specifically highlighted. In addition to traditional uses as herbal remedies, in vitro and in vivo studies focusing on plant extracts and isolated bioactive compounds with anti-*H. pylori* activity are also critically discussed. Lastly, special attention was also given to plant extracts with urease inhibitory effects, with emphasis on involved modes of action.

**Keywords:** plant products; *Helicobacter pylori*; opportunistic colonization; phytopharmacology; in vitro/in vivo findings; anti-urease activity

## 1. Introduction

Plant products, their enriched-derived extracts, and their isolated bioactive molecules have been increasingly studied due to their renowned health attributes, largely used in folk medicine over centuries for multiple purposes [1–9]. Indeed, phytomedicine is garnering much attention among the medical and scientific communities [10–12]. Commercially available synthetic drugs have often been negatively pointed out due to their side effects and related toxicity [13]. In fact, the active molecules used in pharmaceutical formulation are formerly derived from bioactive molecules extracted from plants and other living organisms [14]. Also, a growing number of studies have progressively underlined the multiple bioactive properties conferred by plant formulations [15,16]. Specifically, the antimicrobial effects of multiple plant preparations have been progressively confirmed and supported by both in vitro and in vivo studies and clinical trials [17–21]. Thus, their lower costs, high effectiveness, bioavailability, bioefficacy, and few to no adverse effects have led to intensive research on this topic [22–28].

Among the various opportunistic infections, those caused by *Helicobacter pylori*, a human opportunistic pathogen, is attracting much attention [29]. In fact, it is widely recognized that this bacterium plays an important role in the etiology of peptic and gastric ulcers and even gastric cancers and gastric lymphomas [29]. About half of the worldwide population is colonized by this bacterium, but there are only about 20% who manifest clinical symptoms, which has been linked to the ability of some *H. pylori* strains to both adapt to host's immunological responses and to support an ever-changing gastric environment [29]. Relatedly, increasing rates of antibiotic-resistant *H. pylori* strains have been found, and therefore, the search for new eradication strategies and effective antibiotic therapies has become an issue of crucial importance [30]. Hence, research effort is focused on exploring plants as sources of anti-*H. pylori* agents.

Based on these findings, the present report aims to provide an extensive overview of *Helicobacter pylori* infections, namely describing its involvement in triggering gastric cancer and the most common antimicrobials used in *H. pylori* eradication. Special attention is also given to medicinal plants and their corresponding extracts and isolated constituents used as anti-*H. pylori* agents and urease inhibitors. This review was performed by consulting the databases of PubMed, Web of Science, Embase, and Google Scholar (as a search engine); only full-text available articles were considered, and articles published from 2008 to 2018 were prioritized. The search strategy included the combination of following keywords: "*Helicobacter pylori*", "anti-*Helicobacter*", "medicinal plant", "plant extract", "essential oil", "bioactive", "phytochemical", "antimicrobial", and "eradication".

## 2. *Helicobacter pylori* and Gastric Cancer

*H. pylori* infection has been implicated in the development of gastric cancer, a multifactorial disease and a leading cause of mortality. The risk factors for gastric cancer have been shown to include environmental factors and factors that influence host-pathogen interaction, as well as the complex interplay between these factors [31]. Modern lifestyle, high stress levels, smoking and excessive alcohol consumption, nutritional deficiencies, and prolonged use of non-steroidal anti-inflammatory drugs (NSAIDs) are amongst the most relevant etiological environmental factors [32].

This bacterial infection has been linked to the initiation of chronic gastritis that could later lead to adenocarcinoma of the intestine [33]. However, several mechanisms have been proposed to represent the involvement of *H. pylori* infection in tumorigenesis. Several bacterial virulence factors, such as the cytotoxin-associated gene A (CagA) protein, present in the DNA insertion element Cag pathogenicity island (CagPAI), were found to be of prominent importance in carcinogenesis [34]. Likewise, bacterial peptidoglycan can be delivered into gastric epithelial cells, where it activates a phosphoinositide 3-kinase (PI3K)-Akt pathway leading to cell proliferation, migration, and prevention of apoptosis [35]. Furthermore, *H. pylori*-induced gastric inflammation involves the cyclooxygenase-2 (COX2)/prostaglandin E2 (PGE2) pathway and inflammatory marker interleukin 1 $\beta$  (IL-1 $\beta$ ), which are important factors triggering chronic active gastritis and

adenocarcinoma [31]. Studies have also shown that *H. pylori* infection-induced oxidative stress and DNA damage coupled with dysregulation of E-cadherin/β-catenin/p120 interactions also play critical roles in tumorigenesis [31]. Several environmental and dietary factors have also been suggested to modify *H. pylori*-induced adenocarcinoma [36]. Gastric adenocarcinoma is strongly influenced by dietary salt intake, with high salt intake aggravating tumorigenesis [37].

### 3. Antimicrobials for *H. pylori* Eradication

The success of *H. pylori* eradication markedly depends on the type and duration of treatment, patient compliance to therapy, and antibiotic resistance. For example, because it is difficult to achieve optimal eradication of *H. pylori* infection in patients with peptic ulcers, combinational regimens using two or three antibiotics in addition to a proton pump inhibitor or bismuth are often prescribed to achieve higher eradication rates and to prevent antibiotic resistance emergence [38,39]. These regimens, also known as triple therapies, have cure rates of around 85–90%. They are usually administered for a period of about 10–14 days, in which treatment regimens include the following: (A) bismuth subsalicylate, metronidazole, and tetracycline for 14 days; (B) omeprazole, amoxicillin, and clarithromycin for 10 days; and (C) lansoprazole, amoxicillin, and clarithromycin for either 10 or 14 days.

Unfortunately, the heightening of antimicrobial resistance has been associated with increases in the standard triple therapies failure to eradicate *H. pylori* infection [40]. Hence, research is focusing on developing potent and effective antibacterial regimens that will favor total eradication of the infection. Nonetheless, any eradication treatment comes with some degree of adverse effects, such as nausea, metallic taste, vomiting, skin rash, and diarrhea. Therefore, efforts are being channeled towards the development of effective treatments with few to no side effects.

In the Maastricht V/Florence Consensus Report, 43 experts from 24 countries provided recommendations on the basis of the best available evidence and relevance to the current therapeutic options of management of *H. pylori* infection in the various clinical scenarios [41].

### 4. Plant Extracts and Phytochemicals with Anti-*Helicobacter pylori* Activity

Considering that *H. pylori* infection has been associated with gastrointestinal diseases, including chronic gastritis, peptic ulcer, gastric carcinoma, and mucosa-associated lymphoid tissue lymphoma [42], and that, due to the widespread use of therapeutic agents for the eradication of this bacterium and associated-side effects, increasing rates of *H. pylori* strains with acquired resistance have been discovered. So, the urgent need for alternative has been rekindled and aided by the use of natural drugs [32].

Despite, the newly proposed and used tri-therapy regimens, the cost of acid suppressors and stomach protectors make it inaccessible to the majority of the population [43]. Naturally-derived drugs, including herbs, have been shown to display anti-*H. pylori* activities with minimal side effects, easy accessibility, and affordability [42,44]. In fact, many medicinal plants have been reported in the traditional management of gastrointestinal disorders. Many of these medicinal plants have gone through bioassays to assess their potency against *H. pylori*. Here, the anti-*H. pylori* activity of medicinal plants and isolated bioactive molecules is discussed [45].

Almost all plant parts have been tested for anti-*H. pylori* activity. Plant extract preparations include water (Table 1), essential oils (Table 2), or organic solvents, such as the following: ethanol (Table 3); methanol (Table 4); acetone (Table 5); chloroform (Table 6); petroleum ether (Table 7); methanol/water, ethanol/water, methanol/petroleum, and methanol/dichloromethane extracts (Table 8); and other plant extracts (Table 9).

The susceptibility of *H. pylori* isolates and strains to 543 extracts from 246 plant species was tested by disc diffusion, agar diffusion, agar dilution, and broth microdilution assays. Activity ranged from 1.56–100,000 µg/mL for minimal inhibitory concentration (MIC) and 7–42 mm for inhibition zone diameters (IZDs). However, disparities were observed among the methods used and the tested concentrations: some extracts were tested at very high concentrations (100,000 µg/mL) that might have resulted in biased conclusions. Though many plants (246 species) showed anti-*H. pylori* activity in vitro, very few have been screened for activity in animal models.

Organic extracts of *Carum carvi*, *Xanthium brasiliicum*, and *Trachyspermum copticum* have demonstrated antibacterial activity against 10 clinical isolates of *H. pylori* [46]. In addition, ethanolic extracts of *Cuminum cyminum* and propolis exhibited significant in vitro inhibitory effect against *H. pylori* and, therefore, could be considered a valuable support in the treatment of infection, even contributing to the development of new and safer agents for inclusion in anti-*H. pylori* therapy regimens [47]. Some popular plant species used in Brazilian cuisine and folk medicine in the treatment of gastrointestinal disorders were also investigated for their antibacterial effects, among which *Bixa orellana*, *Chamomilla recutita*, *Ilex paraguariensis*, and *Malva sylvestris* were the most effective against *H. pylori* [48].

Bioactive plant compounds were also tested for their anti-*H. pylori* potency (Table 10), namely those isolated from the *Allium sativum* (cloves), *Convolvulus austro-aegyptiacu* (aerial parts), *Glycyrrhiza glabra* (roots), *Hydrastis canadensis* (rhizomes), *Sanguinaria canadensis* (rhizomes), and *Tinospora sagittata* (aerial parts) species. Berberine, a benzylisoquinoline alkaloid, isolated from *Hydrastis canadensis*, revealed the lowest MIC value (0.78 µg/mL), being therefore considered the most effective bioactive compound, followed by diallyl tetrasulfide (3–6 µg/mL), allicin (4 µg/mL), and palmatine (3.12–6.25 µg/mL) isolated from *Allium sativum* and *Tinospora sagittata*, respectively.

**Table 1.** Plant aqueous extracts with anti-*Helicobacter pylori* activity.

Species	Family	Parts	Anti- <i>H. pylori</i> Potency	Ref.
<i>Acacia nilotica</i> (L.) Delile	Leguminosae	Flowers	MIC = 8–64 µg/mL	[49]
<i>Adhatoda vasica</i> Nees	Acanthaceae	Whole plant	MIC = 16–512 µg/mL	[49]
<i>Alepidea amatymbica</i> Eckl. and Zeyh	Apiaceae	Roots/Rhizomes	IZD = 8.0 ± 8.2 mm	[50,51]
<i>Amphipterygium adstringens</i> (Schltrd.) Standl.	Anacardiaceae	Aerial parts	MIC = 62.5–125 µg/mL	[52]
<i>Annona cherimola</i> Mill.	Annonaceae	Leaves/Stem	MIC = 500 µg/mL	[52]
<i>Artemisia ludoviciana</i> Nutt. subsp. <i>mexicana</i> (Willd. ex Spreng.) Fernald	Compositae	Leaves/stems	MIC = 125 µg/mL IZD = 0–15 mm;	[52]
<i>Bridelia micrantha</i> (Hochst.) Baill.	Phyllanthaceae	Bark	MIC <sub>50</sub> = 48–313 mg/mL; MIC <sub>90</sub> = 78 ≥ 625 µg/mL	[53]
<i>Buddleja perfoliata</i> Kunth	Scrophulariaceae	Aerial parts	MIC = 500 µg/mL	[52]
<i>Calandrinia ciliata</i> (Ruiz and Pav.) DC. (cited as <i>Calandrinia micrantha</i> Schltrd.)	Portulacaceae	Leaves/Stems	MIC = 1000 µg/mL	[52]
<i>Calotropis procera</i> (Aiton) W.T. Aiton	Apocynaceae	Leaves	MIC = 16–256 µg/mL	[49]
<i>Campyloneurum amphostenon</i> (Kunze ex Klotzsch) Fée	Polypodiaceae	Flowers	MIC = 8–256 µg/mL	[49]
<i>Casuarina equisetifolia</i> L.	Casuarinaceae	Aerial parts	MIC = 1000 µg/mL	[52]
<i>Chenopodium incisum</i> Poir. (cited as <i>Teloxys graveolens</i> (Willd.) W. A. Weber)	Amaranthaceae	Fruit	MIC = 128–1024 µg/mL	[49]
<i>Cichorium intybus</i> L.	Asteraceae	Aerial parts	MIC = 250 µg/mL	[52]
<i>Cinnamomum zeylanicum</i> Blume	Lauraceae	Root	IZD < 9 mm	[47]
<i>Cistus laurifolius</i> L.	Cistaceae	Bark	IZD < 9 mm	[47]
<i>Citrus reticulata</i> Blanco	Rutaceae	Flowers	MIC = 62.5–125 µg/mL	[54]
<i>Coccinia hirsutus</i> (L.) Diels.	Menispermaceae	Fruit shell	MIC = 100 µg/mL	[55]
<i>Combretum molle</i> R. Br. Ex G. Don	Combretaceae	Leaves	IZD = 22 mm (200–1000 µg/mL)	[56]
<i>Coriandrum sativum</i> L.	Apiaceae	Bark	IZD = 2.7 ± 5.5 mm	[50,51]
<i>Corydalis yanhusuo</i> W.T. Wang	Papaveraceae	Seed	IJD = 9 mm; MIC = 1.25–5 mg/mL	[47]
<i>Cuminum cyminum</i> L.	Apiaceae	Stem	MIC = 100 µg/mL	[55]
<i>Cuphea aequipetala</i> Cav.	Lythraceae	Seed	IZD < 9 mm	[47]
<i>Cynara scolymus</i> L.	Asteraceae	Aerial parts	MIC = 125 µg/mL	[57]
<i>Cyrtocarpa procera</i> Kunth	Anacardiaceae	Leaves	MIC = 125 µg/mL	[52]
		Bark	IJD = 18 mm; MIC = 1.25–5 mg/mL	[47]
			MIC = 125 µg/mL	[58]

<i>Tinospora sagittata</i> Gagnep. (aerial parts)	Vokensiflavone	14.4–115.7 µM	[97]
	Morelloflavone	14.0–112.3 µM	[97]
	Berberine	0.78–25 µg/mL	[80]
<i>Hydrastis canadensis</i> L. (rhizomes)	β-Hydrastine	25–100 µg/mL	[80]
	Sanguinarine	6.25–50 µg/mL	[80]
	Chelerythrine	25–100 µg/mL	[80]
<i>Sanguinaria canadensis</i> L. (rhizomes)	Protopine	25 ≥ 100 µg/mL	[80]
	Palmatine	3.12–6.25 µg/mL	[42]

MIC, minimal inhibitory concentration.

## 5. In Vivo Findings

*H. pylori* colonization is increasingly being associated with a heightened risk of developing upper gastrointestinal tract diseases. Despite many plant extracts having demonstrated a prominent *H. pylori* inhibition capacity in culture, it is of crucial importance to assess their in vivo efficacy, because it is pivotal to ascertain their effective antibacterial potency. However, a relatively low number of medicinal plants have been investigated to date for in vivo activity, as discussed below.

*Paeonia lactiflora* root extract (100 µg/mL) showed a complete inhibition of *H. pylori* colonization ( $4\text{--}5 \times 10^5$  colony forming unit (CFU)), being the antibacterial potential equivalent to of ampicillin used as positive control (10 µg/mL) ( $2\text{--}4 \times 10^5$  CFU) [98]. Time course viability experiments were also performed in simulated gastric environments to assess the anti-*H. pylori* activity of garlic (*Allium sativum*) oil (16 and 32 µg/mL). A rapid anti-*H. pylori* action in artificial gastric juice was found. Nevertheless, the anti-*H. pylori* activity displayed by garlic oil was noticeably affected by food materials and mucin, despite the fact that a substantial activity remained under simulated gastric conditions [65]. Also, *H. pylori*-inoculated Swiss mice receiving 125, 250, or 500 mg/kg of *Bryophyllum pinnatum* or ciprofloxacin (500 mg/kg) for 7 days, showed a significant reduction of *H. pylori* colonization on gastric tissue from 100% to 17%. In addition, the highest *B. pinnatum* extract tested ( $85.91 \pm 52.91$  CFU) and standard drug ciprofloxacin ( $25.74 \pm 16.15$  CFU) also reduced significantly ( $p < 0.05$ ) the bacterial load of gastric mucosa as compared with untreated infected mice ( $11883 \pm 1831$  CFU) [74]. On the other hand, *Eryngium foetidum* methanol extract ( $381.9 \pm 239.5$  CFU) and positive control ciprofloxacin ( $248 \pm 153.2$  CFU) significantly reduced the bacterial load in gastric mucosa at the same dose (500 mg/kg) compared with untreated and inoculated mice ( $14350 \pm 690$  CFU) [73].

*Hippocratea celastroides* hydroethanolic root-bark extract, a widely used plant against gastric and intestinal infections, also showed anti-*H. pylori* efficacy in naturally infected dogs. In a study of 18 experimental dogs treated with a dose of 93.5–500 mg/kg of *H. celastroides* extract in weight and 19 infected dogs receiving amoxicillin–clarithromycin–omeprazole (control treatment), the results showed effectiveness of 33.3 and 55% in the experimental and control groups, respectively [99].

On the other hand, Ye et al. [95], aiming to investigate the in vivo bactericidal effects of *Chenopodium ambrosioides* L. against *H. pylori*, randomly assigned *H. pylori*-infected mice into plant extract group, triple therapy control (lansoprazole, metronidazole, and clarithromycin), blank control, and *H. pylori* control groups. The obtained eradication ratios, determined by rapid urease tests (RUTs) and histopathology, were, respectively, 60% (6/10) using RUT and 50% (5/10) using histopathology for the test group and both 70% (7/10) for the control group. In addition, the histopathologic evaluation revealed a massive bacterial colonization on the gastric mucosa surface and slight mononuclear cells infiltration after *H. pylori* inoculation, but no obvious inflammation or other pathologic changes in gastric mucosa were stated between the *C. ambrosioides*-treated mice and the standard therapy.

*Tinospora sagittata* and its main component, palmatine, showed in vitro bactericidal effects on *H. pylori* strains, with both MIC and minimal bactericidal concentration (MBC) values of 6250 µg/mL, whereas palmatine's MIC value against *H. pylori* SCYA201401 was 6.25 µg/mL and against *H. pylori* SS1 was 3.12 µg/mL. The time-kill kinetic study evidenced a dose-dependent and progressive decline in the numbers of viable bacteria up to 40 h. *H. pylori*-infected mice treated with extract, palmatine, or control therapy (omeprazole, clarithromycin, and amoxicillin), presented eradication ratios of, respectively, 80%, 50%, and 70%. The anti-*H. pylori* activity found in *T. sagittata* extracts and its major constituent, palmatine, both in culture and animal models, clearly highlights the antibacterial potential of this plant in the treatment of both infected humans and animals [42].

Total alkaloids fraction activity (TASA) of *Sophora alopecuroides* L., widely used in herbal remedies against stomach-associated diseases, were also investigated on 120 *H. pylori*-infected BALB/c mice mouse gastritis. A total of 100 infected mice were randomly assigned into 10 treatment groups: group I (normal saline); group II (bismuth pectin); group III (omeprazole); group IV (TASA 2 mg/day); group V (TASA 4 mg/day); group VI (TASA 5 mg/day); group VII (TASA + bismuth pectin); group VIII (TASA + omeprazole); group IX (bismuth pectin + clarithromycin + metronidazole); and group X (omeprazole + clarithromycin + metronidazole). The mice were sacrificed 4 weeks after treatment. Real-time PCR was used to detect 16sDNA of *H. pylori* to test both the colonization and mice clearance of bacteria of each treatment. Hematoxylin and eosin staining and immunostaining of mice gastric mucosa were also used to observe the general inflammation and related factors: IL-8, COX2, and nuclear factor-kappa B (NF- $\kappa$ B) expression changed after treatments. TASA combined with omeprazole or bismuth pectin showed promising antimicrobial activity against *H. pylori*, as well as conventional triple therapy. Indeed, hematoxylin and eosin staining and immune-staining of mice gastric mucosa evidenced that the inflammation on mice gastric mucosal membrane were also clearly relieved in TASA combined treatments and conventional triple therapy compared with normal saline-treated mice. Accordingly, from immunohistochemistry results, *H. pylori*-induced IL-8, COX2, and NF- $\kappa$ B were consistently suppressed in the seventh, eighth, ninth, and tenth groups to a certain extent [100].

Pastene et al. [101] investigated the inhibitory effects of a standardized apple peel polyphenol-rich extract (*Malus pumila* Mill., cited as *Malus domestica*) against *H. pylori* infection and vacuolating bacterial toxin (VacA)-induced vacuolation and found that the preparation significantly prevented vacuolation in HeLa cells with an IC<sub>50</sub> value of 390  $\mu$ g gallic acid equivalents (GAE)/mL and an in vitro anti-adhesive effect against *H. pylori*. A significant inhibition was also stated with 20–60% reduction of *H. pylori* attachment at concentrations between 0.250 and 5 mg GAE/mL. In a short-term infection model (C57BL6/J mice), doses of 150 and 300 mg/kg/day showed an inhibitory effect on *H. pylori* attachment. Orally administered apple peel polyphenols also showed an anti-inflammatory effect on *H. pylori*-associated gastritis, lowering malondialdehyde levels and gastritis scores.

Kim et al. [102] investigated the GutGard™ ability (a flavonoid rich, *Glycyrrhiza glabra* root extract) to inhibit *H. pylori* growth both in Mongolian gerbils and C57BL/6 mouse models. Infected male Mongolian gerbils were orally treated once daily 6 times/week for 8 weeks with 15, 30, and 60 mg/kg GutGard™. Bacterial identification in the biopsy samples of gastric mucosa, via urease, catalase, and ELISA, as well as immunohistochemistry revealed a dose-dependent inhibition of *H. pylori* colonization in gastric mucosa by GutGard™. As well, the administration of 25 mg/kg GutGard™ in *H. pylori*-infected C57BL/6 mice significantly reduced *H. pylori* colonization in gastric mucosa, suggesting its usefulness in *H. pylori* infection prevention.

*Calophyllum brasiliense* stem bark preparations are popular remedies for the treatment of chronic ulcers. A current report evidenced gastroprotective, gastric acid inhibitory properties and anti-*H. pylori* activity in culture (MIC = 31  $\mu$ g/mL) [75]. Hydroethanolic (50, 100, and 200 mg/kg) and dichloromethane (100 and 200 mg/kg) fractions-treated Wistar rats ulcerated by acetic acid and inoculated with *H. pylori*, showed a marked delay in ulcer healing and reduced the ulcerated area in a dose-dependent manner [75]. While the dichloromethane fraction, at 200 mg/kg, increased PGE2 levels, both the hydroethanolic and dichloromethane fractions decreased the number of urease-positive animals, as confirmed by the reduction of the *H. pylori* presence in histopathological analysis. This aspect suggests that the antiulcer activity of *C. brasiliense* is partly linked with its anti-*H. pylori* efficacy [75]. Also, phenolic-rich oregano (*Origanum vulgare*) and cranberry (*Vaccinium macrocarpon*) extracts showed a prominent ability to inhibit *H. pylori* through urease inhibition and disruption of energy production by inhibition of proline dehydrogenase at the plasma membrane [103].

## 6. Urease Inhibition

The current therapies are challenged by the considerable number of emerging *H. pylori*-resistant strains. This fact has driven the need for alternative anti-*H. pylori* therapies that ideally should have good stability and low toxicity and to be able to inhibit urease activity [62]. It has been shown that *H. pylori* urease activity is crucial in bacterial survival and pathogenesis [104].

The inhibitory potency of some anti-*H. pylori* medicinal plants has been reported [62] and even investigated by some authors in the involved mechanisms of antibacterial action of those plant products [63].

Table 11 briefly shows the studied plant extracts with prominent anti-urease activity. Amin et al. [49] demonstrated that the methanolic and acetone extracts of some medicinal plants were able to inhibit urease activity. In fact, *Acacia nilotica* flower methanol and acetone extracts evidenced anti-*H. pylori* activity, being MIC values of 8–64 µg/mL and 4–64 µg/mL, respectively. Both extracts inhibited urease activity at 8.2–88.2% and 9.2–86.6%. *Calotropis procera* leaf and flower methanol and acetone extracts, with MIC values of 16–256 µg/mL, 32–256 µg/mL, and 8–128 µg/mL also displayed urease inhibitory effects, being, respectively, 12.2–48.2% and 7.2–58.2% for leaf and 9.3–68.2% for flower acetone extracts [49]. While *A. nilotica* extract exerted a competitive inhibition, that of *C. procera* extract displayed a mixed type of inhibition [49]. In addition, *Casuarina equisetifolia* fruit methanol extract, with MIC values varying from 128–512 µg/mL, also displayed 12.2–86.2% inhibition of urease activity [49].

In another study, *Camellia sinensis* young non-fermented and semi-fermented shoot extracts, presented inhibition zone diameter (IZD) and MBC of, respectively, 22.5 mm at 20–60 µg/disk and 4 mg/mL, and 18 mm at 20–60 µg/disk and 5.5 mg/mL. They both inhibited Ure A and Ure B subunits production at 2.5 and 3.5 mg/mL [94]. Also, the *Chamomilla recutita* flower extract, which inhibited *H. pylori* growth at an MIC<sub>90</sub> value of 125 mg/mL and a MIC<sub>50</sub> value of 62.5 mg/mL, was able to inhibit the urease production [105]. In the same line, the methanol fraction of *Euphorbia umbellata* bark extract inhibited both *H. pylori* growth (44.6% inhibition) at 256 µg/mL and urease activity (78.6% inhibition) at 1024 µg/mL [77]. Moreover, the *Peumus boldus* flower aqueous extract showed anti-adherent activity against *H. pylori* and inhibited urease activity with an IC<sub>50</sub> value of 23.4 µg GAE/mL [61]. The aqueous extract of *Terminalia chebula* fruit showed activity with MIC and MBC values of 125 mg/mL and 150 mg/mL, respectively, and inhibited *H. pylori* urease activity at a concentration of 1–2.5 mg/mL [63].

**Table 11.** Urease inhibitory potential of plant extracts.

Plant Species	Parts	Extraction Solvent	Concentration Tested	Urease Inhibition	Ref.
<i>Acacia nilotica</i> (L.) Delile	Leaves	Methanol	8–128 µg/mL	8.21–88.21%	[49]
	Flowers	Acetone	8–128 µg/mL	9.20–86.56%	[49]
<i>Calotropis procera</i> (Aiton) W.T. Aiton	Leaves	Methanol	16–256 µg/mL	12.23–48.22%	[49]
	Leaves	Acetone	32–256 µg/mL	7.23–58.21%	[49]
	Flowers	Acetone	8–128 µg/mL	9.33–68.21%	[49]
<i>Camellia sinensis</i> (L.) Kuntze	Young shoots	Methanol: water (62.5:37.5 v/v)	2.5 mg/mL	100% Ure A and B	[94]
		non-fermented extract			
		Methanol: water (62.5:37.5 v/v))	3.5 mg/mL	100% Ure A and B	[94]
<i>Casuarina equisetifolia</i> L.	Fruit	Methanol	128–512 µg/mL	12.21–86.21%	[49]
	Flowers	Olive oil	31.25–250 mg/mL	Inhibited urease production	[105]
<i>Euphorbia umbellata</i> (Pax) Bruyns	Bark	Methanol	1024 µg/mL	78.6%	[77]
<i>Peumus boldus</i> Mol.	Leaves	Water		$IC_{50} = 23.4 \mu\text{g GAE/mL}$	[61]
<i>Terminalia chebula</i> Retz	Fruit	Water	1–2.5 mg/mL	Inhibited urease activity	[63]

IC<sub>50</sub>, 50% inhibitory concentration. GAE, gallic acid equivalents.

## 7. Conclusions and Future Perspectives

Overall, the report suggests that the studied plant extracts possess anti-*H. pylori* activity, strengthening the claims made by traditional medicine practitioners about their putative anti-ulcerative properties. However, very few of them were investigated for efficacy in animal models or the ability to inhibit urease activity. Further studies are warranted for efficacy studies in animal models, elucidation of effective modes of action (including urease inhibition), and clinical trials in human being.

**Author Contributions:** All authors contributed equally to this work. B.S., J.S.-R., P.V.T.F., and N.M. critically reviewed the manuscript. All the authors read and approved the final manuscript.

**Funding:** The APC was funded by N Martins.
