

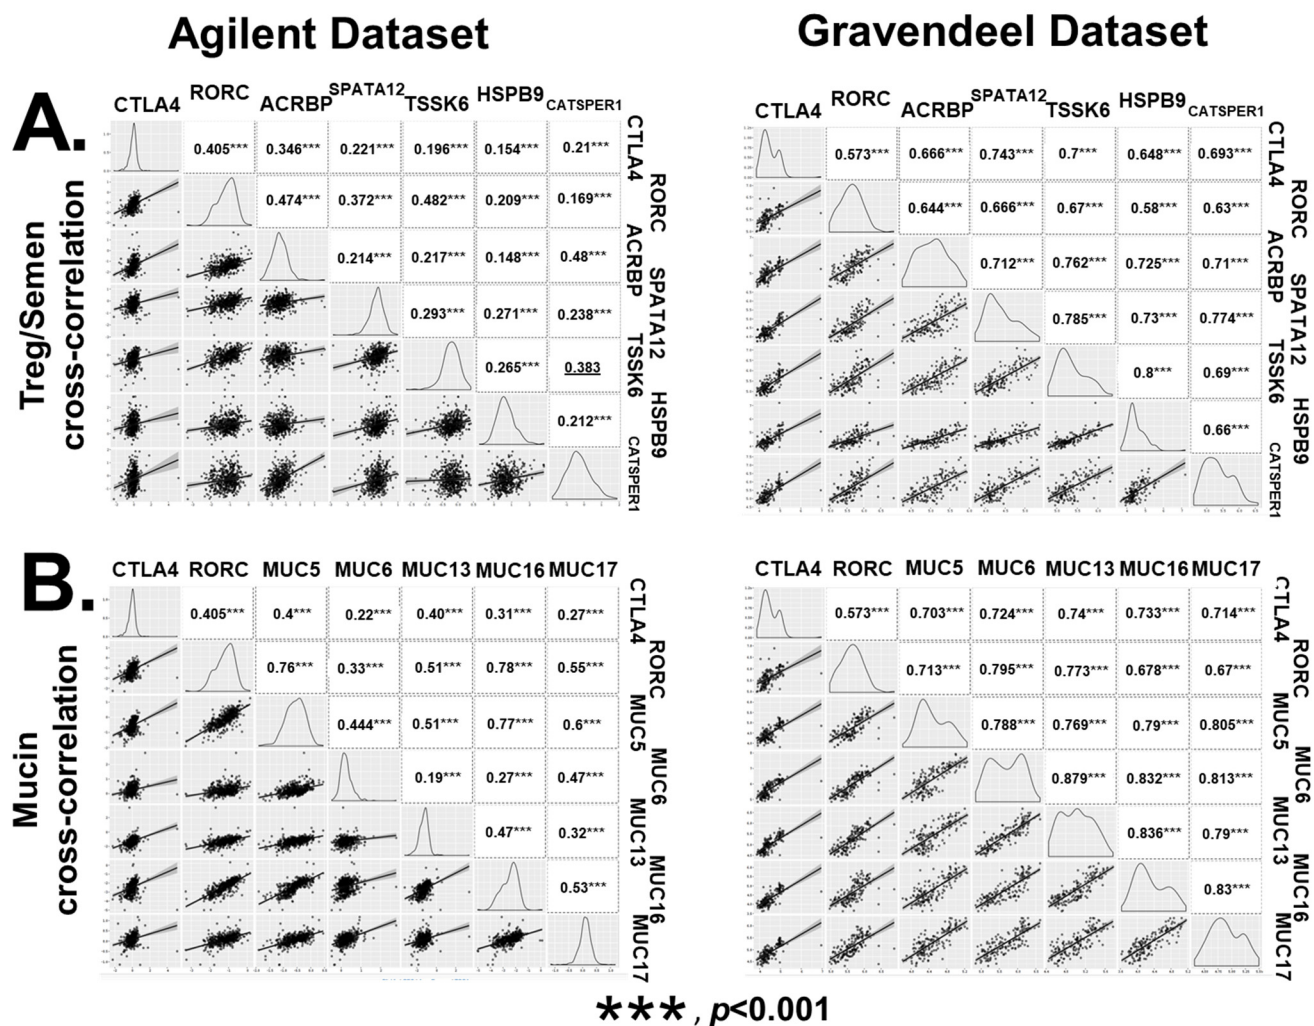

**Figure S1. Cross-Correlation of Selected Hypoxia Response Genes (HiF) and RORC-Treg Genes in GBM:** The cross-correlations of *SLC2A1*, *SLC2A3*, *ADM*, *VLDLR* and *VEGFA* (**Figure S1A.**) with *FOXP3*, *CTLA4*, *GITR*, *RORC* and *GATA3* (**Figure S1B.**) Transcription levels of wild-type IDH GBM tumors, drawn from Agilent, on the left, and Gravendeel, on the right, databases.  $p < 0.001$  in all cases. Images generated using Gliovis.

**Figure S2. Cross-correlation of CTLA4 and RORC with male-specific and mucin genes in GBM:** In Fig S2A the cross-correlations of *CTLA4* and *RORC* with the sperm specific genes *ACRBP*, *SPATA12*, *TSSK6*, *HSPB9*, and *CATSPER1*. In Fig S2B the cross-correlations of *CTLA4* and *RORC* with the mucin genes *MUC5B*, *MUC6*, *MUC13*, *MUC16* and *MUC17* are shown. These genes are native to both testicle and semen, both known to be rich with RORC-Tregs. The highly significant cross-correlations with *CTLA4* and *RORC* would suggest this RORC-Treg subtype is reconstituted in GBM. Transcription levels of wild-type IDH GBM tumors, drawn from Agilent, on the left, and Gravendeel, on the right, databases.  $p < 0.001$  in all cases. Images generated using Gliovis.

## U133 Dataset

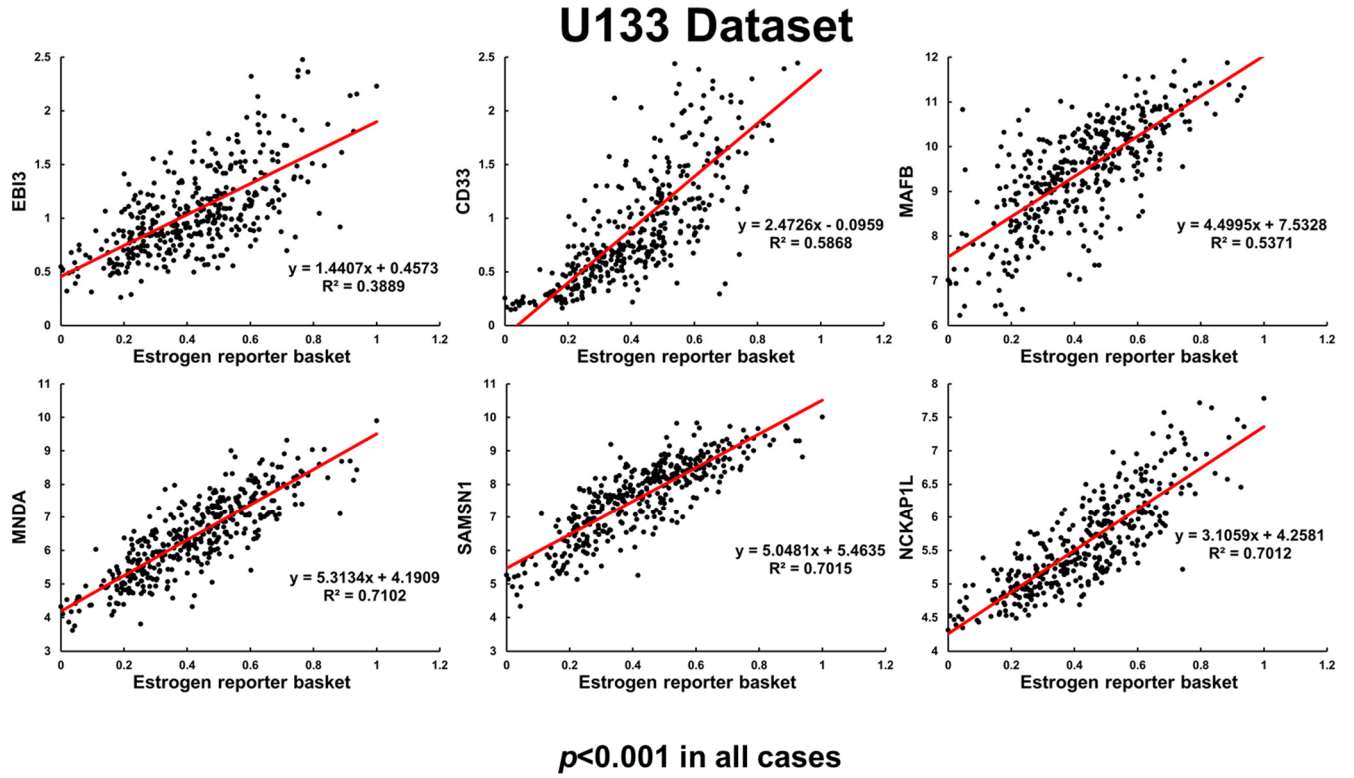

Figure S3. Cross-correlation of RORC-Treg genes with androgen report gene *KRT37*, in GBM: The cross-correlations of individual RORC-Treg markers and Tregs with androgen responsive gene *KRT37*. GBM tumors, wild-type IDH, were drawn from the U133 Firehose Legacy database; correlations are  $p < 0.001$  in all cases.

## U133 Dataset

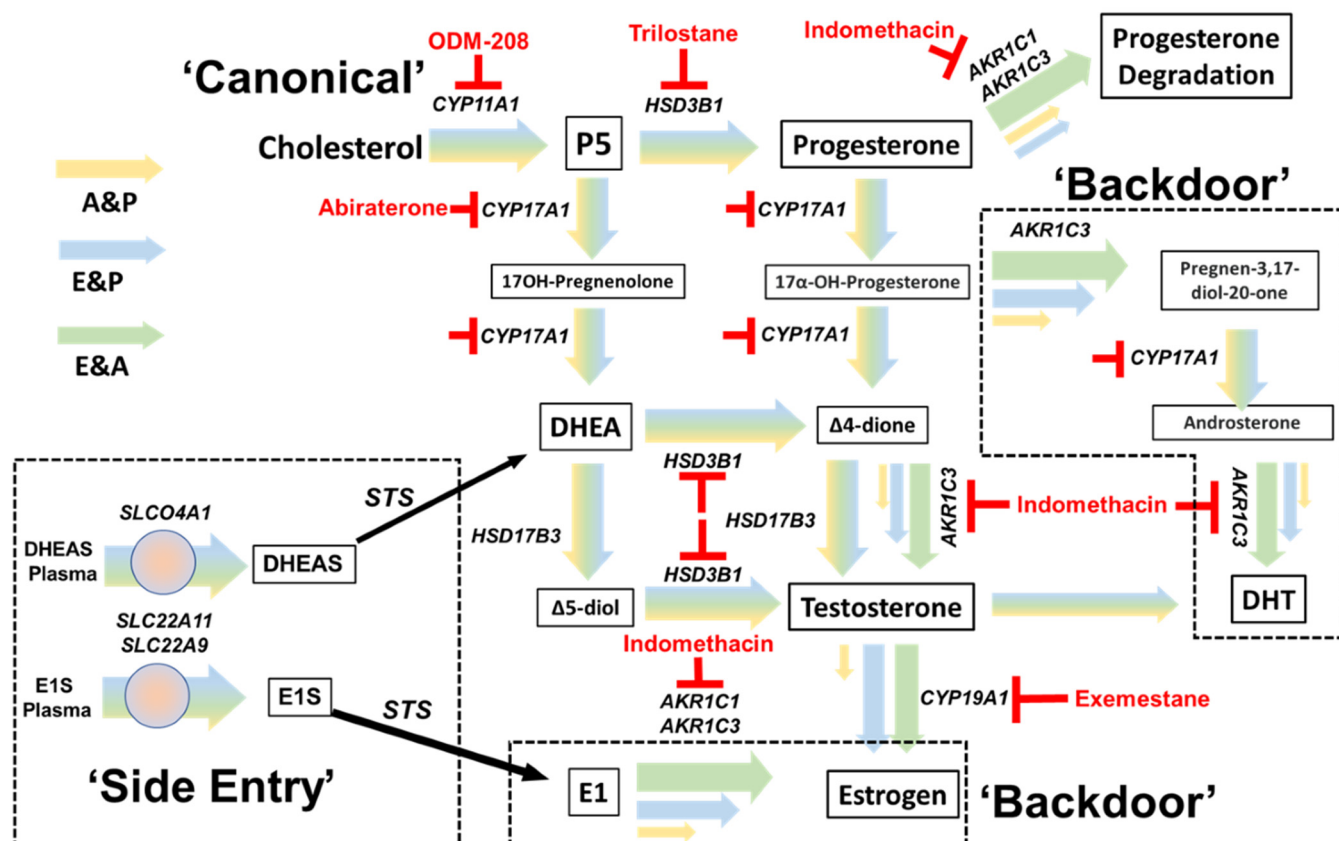

**$p < 0.001$  in all cases**

**Figure S4. Cross-correlation of estrogen sensitive genes in GBM:** The cross-correlations of GBM tumor mRNA levels of estrogen gene proxies with the calculated 'Estrogen reporter basket': derived by the averaged/normalized levels of the five estrogen reporter genes. Data for GBM transcriptome, wild-type IDH, were drawn from the U133 Firehose Legacy database and correlations are  $p < 0.001$  in all cases.

**Figure S5. Cross-correlation of MDSC/TAM markers and estrogen reporter basket in GBM:** The cross-correlations of MDSC and TAM gene markers with synthetic 'Estrogen' series derived from the averaged rescaled mRNA levels of estrogen responsive genes. GBM tumors, wild-type IDH, were drawn from the U133 Firehose Legacy database and correlations are  $p < 0.001$  in all cases. MDSC= myeloid derived suppressor cell; TAM= tumor associated macrophage.

**Figure S6. Steroid Synthesis Pathway with Enzyme Inhibitors:** Depiction of classical, backdoor and side entry steroid synthesis pathways with inhibitors in red. Yellow denotes high androgen/progesterone; low estrogen (A&P), blue denotes high estrogen/progesterone; low androgen (E&P), and green denotes high estrogen/androgen; low progesterone (E&A). Arrow size correlates directly with level of upregulation. Tricoloured arrows designate equal upregulation among all three groups. **Canonical:** Cholesterol converts to P5 via CYP11A1, inhibitable by ODM-208. CYP17A1 converts P5 to 17OH-pregnenolone and then into DHEA, blockable by abiraterone. DHEA then converts into  $\Delta^5$ -diol by AKR1C3 or HSD17B3, and further converted to testosterone via HSD3B1, inhibitable by trilostane. DHEA can also be converted to  $\Delta^4$ -dione via HSD3B1, further converted to testosterone by AKR1C3 or HSD17B3, and proceeds to DHT via SRD5A or AKR1C3. **Side entry/Backdoor:** GBMs also use the fetal androgen synthesis pathway. The 'side entry' pathway starts with DHEAS and E1S with SLCO4A1, SLC22A11, SLC22A9 and STS, used to convert DHEAS to DHEA to  $\Delta^4$ -dione to testosterone, estrogen and DHT. The backdoor pathway starts with a diversion of the 17- $\alpha$ -OH-progesterone into pregnen-3,17-diol-20-one via AKR1C3. CYP17A1 generates androsterone which is converted into DHT by AKR1C3, bypassing the canonical testosterone route. This also converts estradiol to estrone via aldo-keto reductases 1 and 3, both inhibitable by indomethacin.

## Gall Bladder Surgery Control Serum

## GBM Surgery Serum

**Figure S7. Monkey Testicle labeled with GBM and Control Patient Serum:** Patients serum anti-testicular antibodies assayed using fixed cynomolgus monkey testicle slices. Top two rows consist of serum from control patients, showing low levels of anti-sperm/testicular antibodies, less brown staining. The next three rows are GBM patient serum, showing evidence of antibodies to testicular germ cells, seen deeply stained (brown).

**Table S1.** Characteristics of stratification of GBM tumors by HiF and Treg fractionation, we  $p$ -values derived from t-tests performed against the neither cohort.
