

Longitudinal proteomic analysis of plasma across healthy pregnancies reveals indicators of gestational age

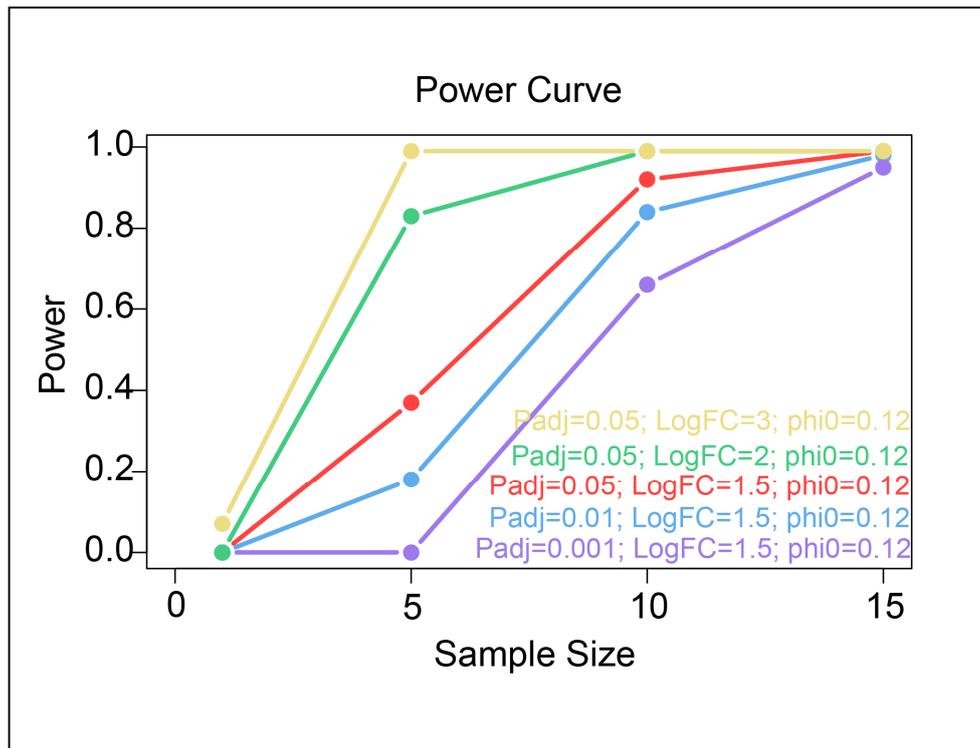

Figure S1: The relationship between power and sample size, at $P_{adj} = 0.001, 0.01$ or 0.05 for $\log_{2}FC = 1.5, 2, \text{ or } 3$, in protein expression. It is clear from these curves that with the data median dispersion (dispersion = 0.12 from our pilot study), significance level, and sample size have a profound effect on power. As clinical sample numbers were limited, the power curve at p -adjusted = 0.05 was an appropriate choice for our study. Using this curve, it was estimated that biological replicates of ten, per experimental group, result in $\geq 80\%$ of chance of detecting a fold change of 1.5- and above. Thus, we designed this study, taking $n = 11$ for each experimental group.
