Change-point analysis: +/- indicates the direction of each species response (positive/negative) to a gradient, standardized *z*-scores, observed change points (Obs.) with bootstrap confidence intervals (5 and 95%) based on 500 bootstrap replicates. Indicator species analysis: indicator value scores (IndVal) with corresponding *p*-values and estimates of purity (i.e., mean proportion of correct response

direction (z- or z+) assignments) and reliability (i.e., mean proportion of  $p \leq 0.05$ ) based on 500 replicates. Species in bold are credible indicator species with purity > 0.90 and reliability > 0.75 for the respective gradient.
