## Alignments multiple of amino acid sequences corresponding to precursors from putative venom components inferred from the transcripts obtained from the tentacles of *A. dowii*.

In all the alignments, the region corresponding to the signal peptide is highlighted in orange, in green is highlighted the region of propeptide and in blue is highlighted the region of mature protein. In some cases, the conserved Cys residues are highlighted in bold blue and in bold letters. The number of amino acids (aa) and the percentages of identity (I%) are calculated considering only the regions of the mature protein, this last value is calculated with the program LALIGN version 2.1.30 and with respect to the sequence indicated with 100% identity in the alignment. In some cases, the percentage of similitude (%S) also is showed, this value also calculated with the program LALIGN version 2.1.30 and considering only the regions of the mature protein and with respect to the sequence indicated with 100% similarity in the alignments. All alignments were made with ClustalX 2.1 and the characters (\*), (:), (.) are shown in the low region along the alignments to indicate positions with fully conserved residues, positions with conservative substitutions and positions with less conservative substitutions, respectively.

### A) Sea anemone type 1 potassium channel toxin family. Type 1b subfamily.
