Text S1. Additional information on the inverse probability weighting analysis

Methods

For addressing bias caused by differential loss to follow-up, inverse probability weighting method [1] was used to examine the impact of differential loss to follow-up in the present study. The reasons of loss to follow-up were divided into death and other causes (e.g., refusal and inability to contact), and because determinants of death and loss to follow-up for other causes may be different, we separately modeled attrition due to death and attrition due to other causes.

First, each observation's probability of death (P1) and loss to follow-up due to other causes (P2) in each wave of follow-up were estimated by generalized estimating equation (GEE) regression models with death (yes / no) and loss to follow-up due to other causes (yes / no) as outcomes, including baseline time-constant covariates (sex, education level, years lived in Hong Kong and Community Screening Interview for Dementia), time-varying covariates (age, marital status, alcohol drinking, smoking, living alone, self-rated health, depression, Mini-Mental State Examination and number of chronic diseases), level of baseline total physical activity and built environment class as predictors. Non-stabilized inverse probability weighting was calculated as $1 / (P1 * P2)$. As the reciprocal of a probability, some observation's probability may potentially be very large for participants with a small probability of staying alive and being in follow-up. We further calculated stabilized weights.

Second, each observation's probability of death (S1) and loss to follow-up due to other causes (S2) in the study were estimated by GEE regression models with death (yes / no) and loss to follow-up due to other causes (yes / no) as outcomes, including sex, education level, years lived in Hong Kong, Community Screening Interview for Dementia, marital status, alcohol drinking, smoking, living alone, self-rated health, depression, Mini-Mental State Examination and number of chronic diseases (only baseline time-constant covariates) as predictors. Stabilized weights were calculated as $(S1 * S2) / (P1 * P2)$, and used in the main analyses.

N. max		0.72	0.58	0.53	0.36	0.29	0.32	0.28	0.30

AIC, Akaike Information Criterion; BIC, Bayesian Information Criterion; SSA-BIC, Sample-size-adjusted BIC: lower values on these fit statistics indicate better model fit.

BLRT, Bootstrap Likelihood Ratio Test: comparing the improvement between neighboring class models.

Entropy: a measure of the precision of classification, higher value indicates greater precision.

Prob. min / max: minimum / maximum of the average latent class probabilities for most likely class membership by assigned class.

N. min / max: proportion of the sample assigned to the smallest / largest class (based on most likely class membership).

Table S2. Adjusted HR (hazard ratio) and 95%CI (confidence interval) of attrition due to loss to follow-up over the study period ^a

	Adjusted HR (95% CI)	
	Death (case = 3944; observation = 9921)	Other causes (case = 3466; observation = 8622)

^a β (95% confidence interval) were estimated from weighted linear mixed-effects models.

Model 3: including age, built environment class and their interaction term (age*built environment class), and adjusted for sex, marital status, education level, alcohol drinking, smoking, years lived in Hong Kong, living alone, self-rated health, depression, Mini-Mental State, Examination Community Screening Interview for Dementia, number of chronic diseases and level of baseline total, leisure, household and walking physical activity, respectively.

Model 3a: repeated analyses of model using unweighted linear mixed-effects models;

Model 3b: repeated analyses of model after excluding participants who reported moving from the baseline address during follow-up;

Model 3c: repeated analyses of model after excluding participants who loss to follow-up within 4 years after baseline;

Model 3d: repeated analyses of model after excluding observation in 2015-2017 follow-up;

Model 3e: repeated analyses of model after excluding participants who reported a functional impairment.

* P -value < 0.05, ** P -value < 0.01, *** P -value < 0.001

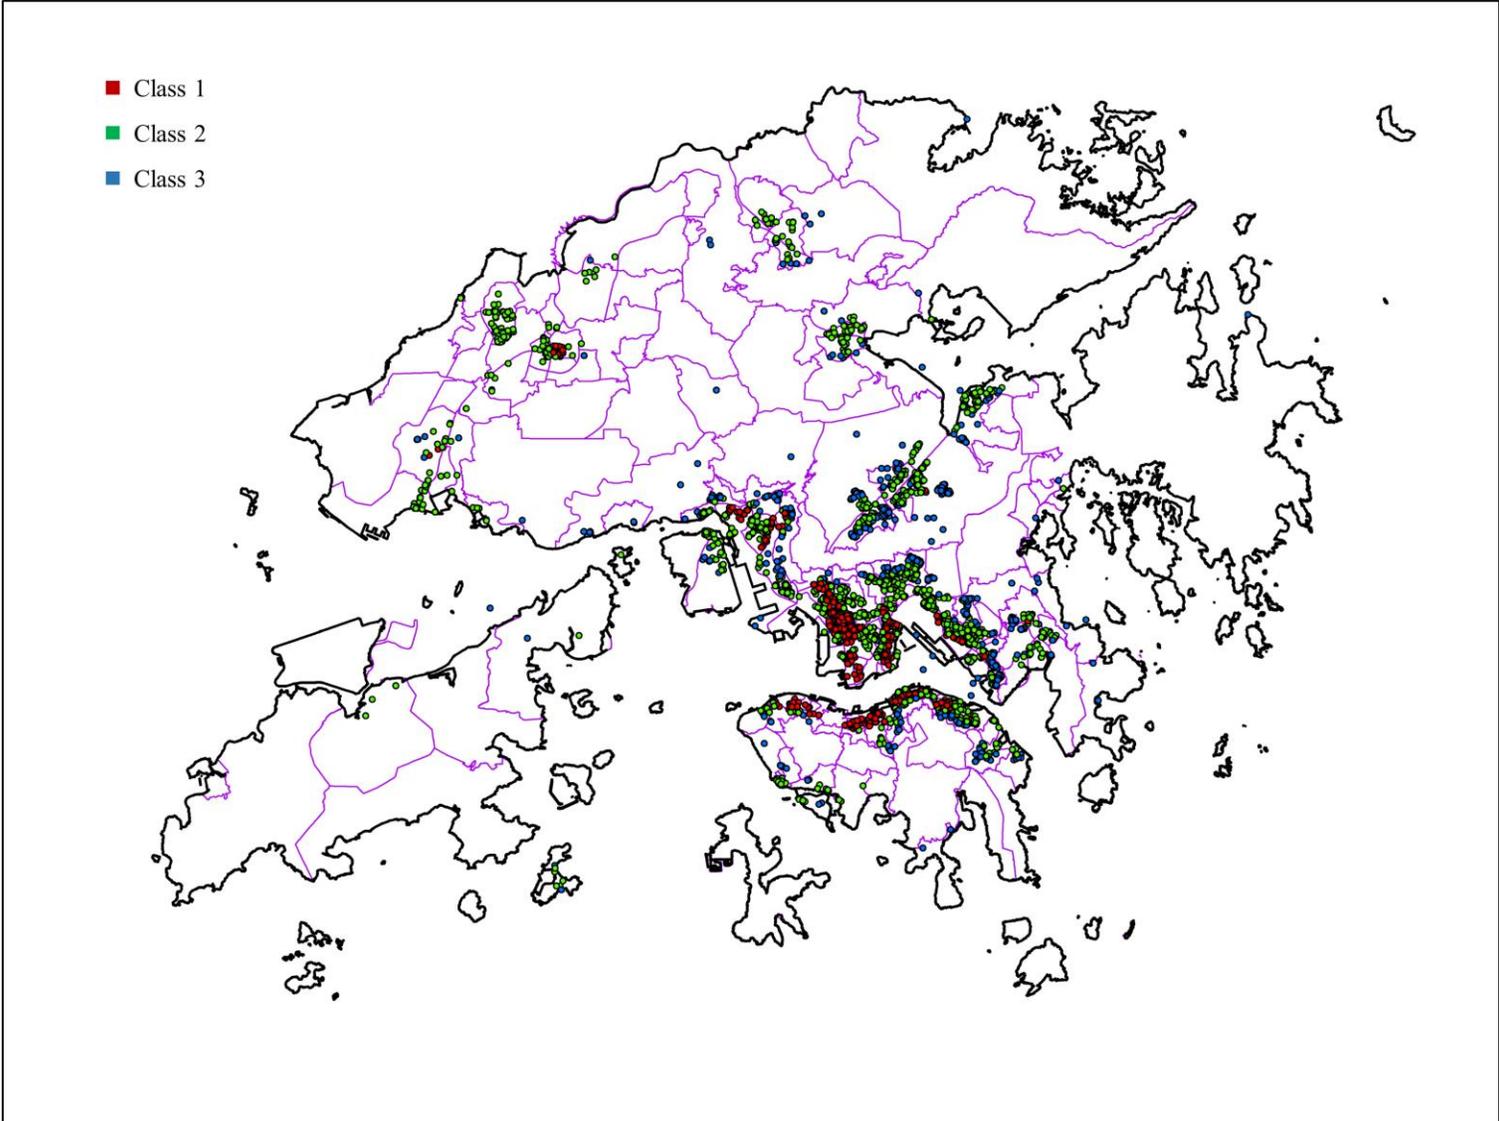

Figure S1. Geographical distribution of the participants' addresses at baseline.
