**Figure S1. AcMNPV variants.** The ORF of the *p74* gene of AcMNPV, SeMNPV and HearSNPV were used alone or combining sectors corresponding to the protein amino and carboxyl terminals. **A.** Illustration showing the composition of the different donor plasmids generated containing the *p74* variants and GFP, or polyhedrin and mCherry. Grey dotted line represents the BamHI recognition site between the amino and carboxyl P74 protein domains. **B.** Illustration showing bacmids deficient in the *p74* gene (indel mutation by CRISPR/Cas9 technology and NHEJ) after Bac-to-Bac complementation, one contributing with polyhedrin and the other one with a P74 variant. When both are coinfecting in the same cells OBs can be generated with *per os* infective potential.

**Figure S2. Infectivity of complemented AcMNPV p74 knockout.** *R. nu* larvae exposed to virions derived from AcMNPV knocked out in *p74* and supplemented with the ORF variant of the same virus carrying the point mutation to introduce the BamHI site. Photographs (0.8X) taken 120 hours after treatment with the virus through *per os* route showing the appearance of a larva in bright field (A.), and the mCherry (B.) and GFP (C.) expression.
