

Supplementary Figures

Figure S1. Schematic depiction of novel viral genomes discovered in vampire bats. Open reading frames are represented as colored arrows. Only complete or near complete genomes are shown.

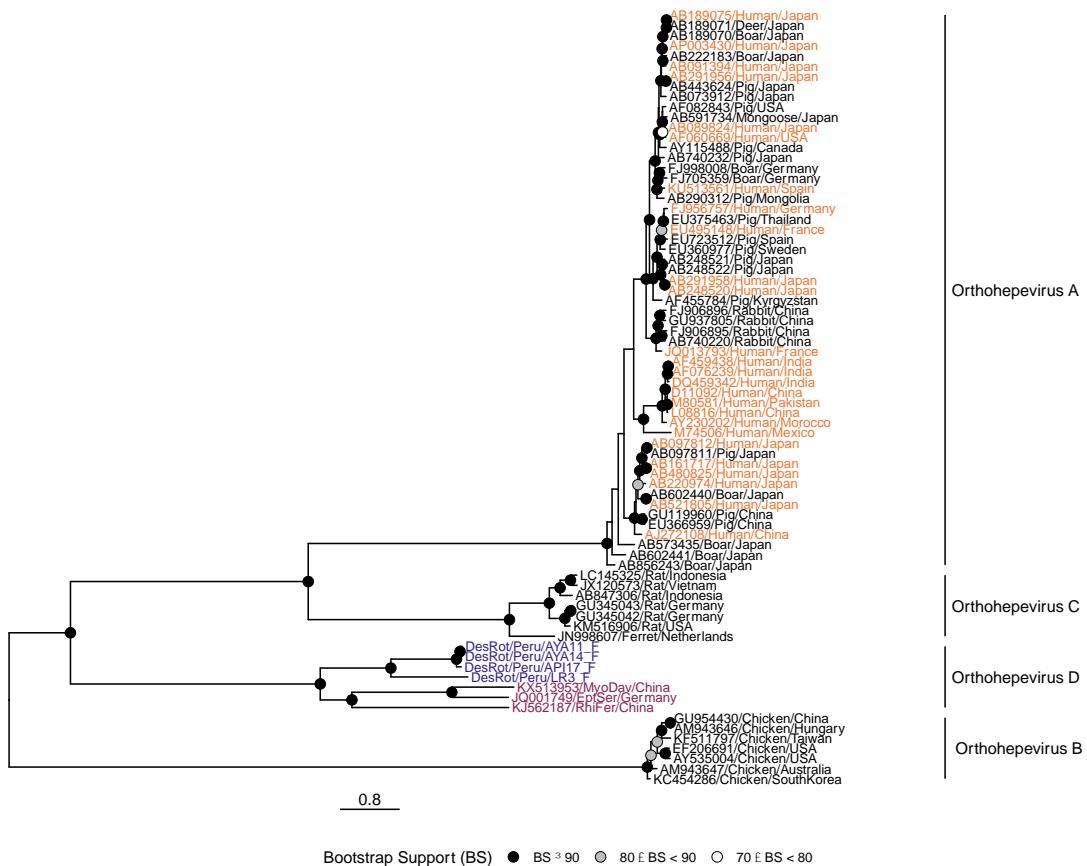

Figure S2. Hepieviridae full genome phylogeny. The maximum likelihood phylogeny was based on a 6,038 nucleotide alignment of 76 complete genome sequences. Phylogenetic analysis was performed in RAxML using the GTR+I+G substitution model and 100 bootstrap replicates. Sequences are colored to indicate vampire bat-associated HEV sequences (indigo), other bat-associated sequences (purple), human-associated sequences (orange) and sequences from other hosts (black). ICTV recognized species are shown along the right of the tree. The scale bar represents the mean number of substitutions per site.

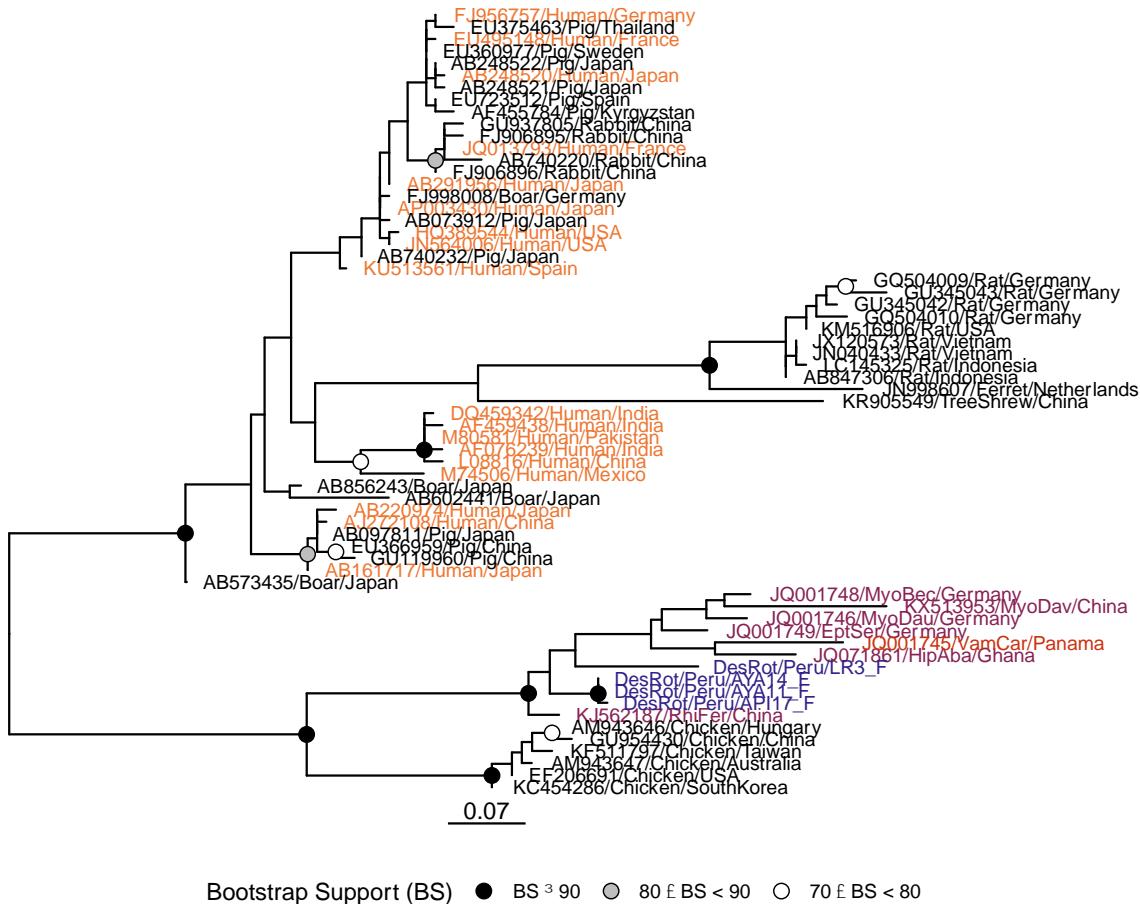

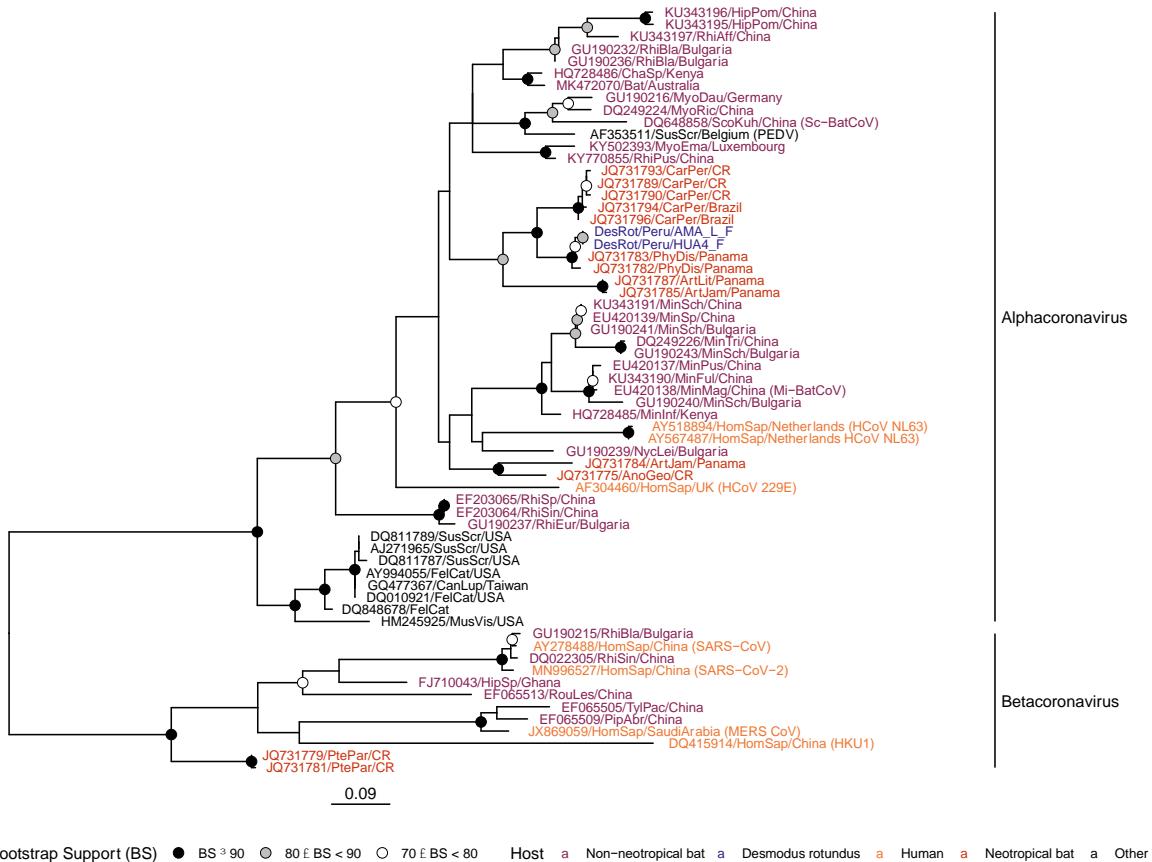

Figure S3. Hepeviridae RdRp phylogeny. The maximum likelihood phylogeny was based on a 109 amino acid alignment of 65 RdRp sequences (ORF1-1419-ORF1-1527). Phylogenetic analysis was performed in RAxML using the LG+G substitution model and 100 bootstrap replicates. Sequences are colored to indicate vampire bat-associated HEV sequences (indigo), sequences associated with other Neotropical bats (red), non-Neotropical bat-associated sequences (purple), human-associated sequences (orange) and sequences from other hosts (black). The scale bar represents the mean number of substitutions per site.

Bootstrap Support (BS) ● BS > 90 ○ 80 ≤ BS < 90 ○ 70 ≤ BS < 80 Host a Non-neotropical bat a Desmodus rotundus a Human a Neotropical bat a Other

Figure S4. Coronaviridae RdRp phylogeny. Maximum likelihood tree based on a 272 amino acid alignment of 63 RdRp sequences including vampire bat-associated CoV sequences (indigo), Neotropical bat-associated sequences (red), non-Neotropical bat-associated sequences (purple), human-associated sequences (orange) and sequences from other hosts (black). ICTV recognized CoV species are shown in parentheses following each branch tip name, and genera are shown on the right of the tree. Phylogenetic analysis was performed in RAxML using the LG+I+G substitution model and 1000 bootstrap replicates. The scale bar represents the mean number of substitutions per site.

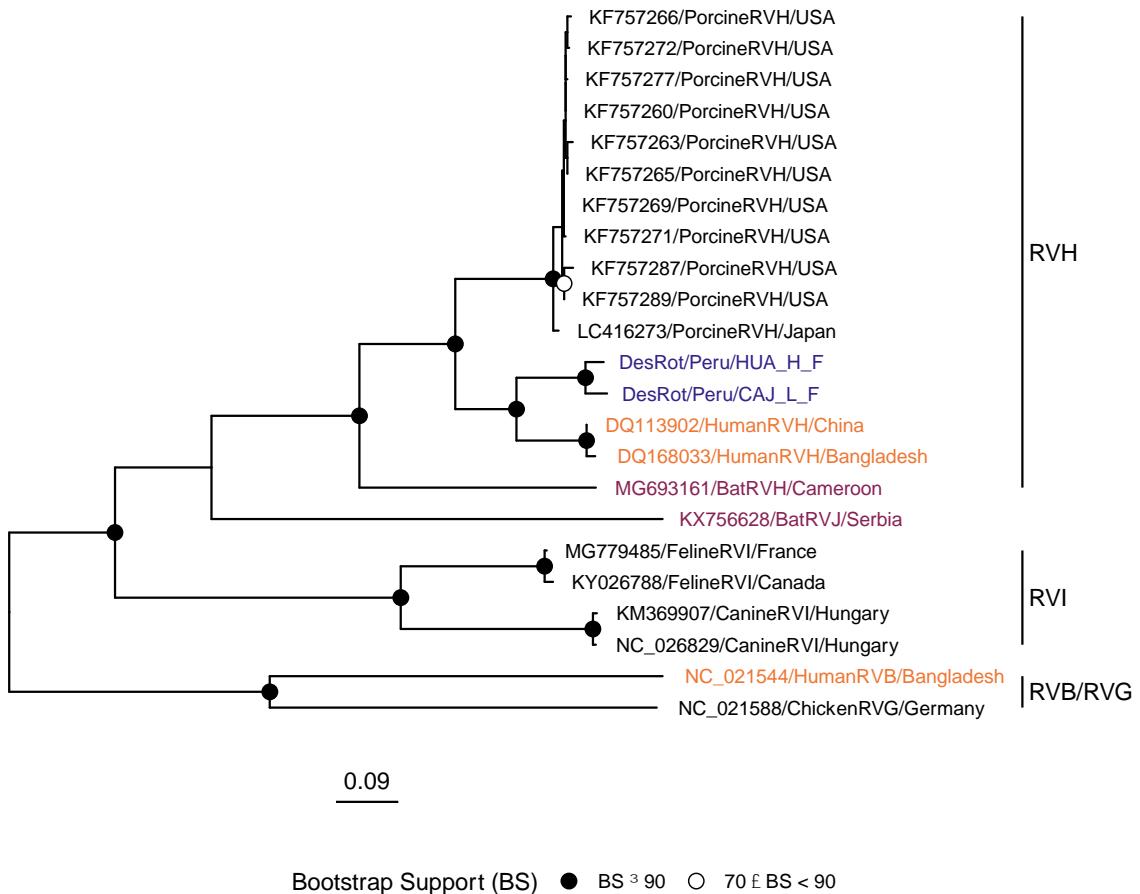

Figure S5. Reoviridae VP6 phylogeny. Maximum likelihood tree based on a 398 amino acid alignment of 22 sequences of the VP6 gene. Phylogenetic analysis was performed in RAxML using the LG+G+F substitution model and 100 bootstrap replicates. Analyses included two vampire bat-associated RVH sequences (indigo), other bat-associated RV sequences (purple), human-associated sequences (orange), and RV sequences from non-bat hosts (black). Although some antigenic types shown in the tree (RVG, RVH, RVI) are not yet formally recognized by the ICTV, they are shown on the right of the tree for context. The scale bar represents the mean number of substitutions per site.

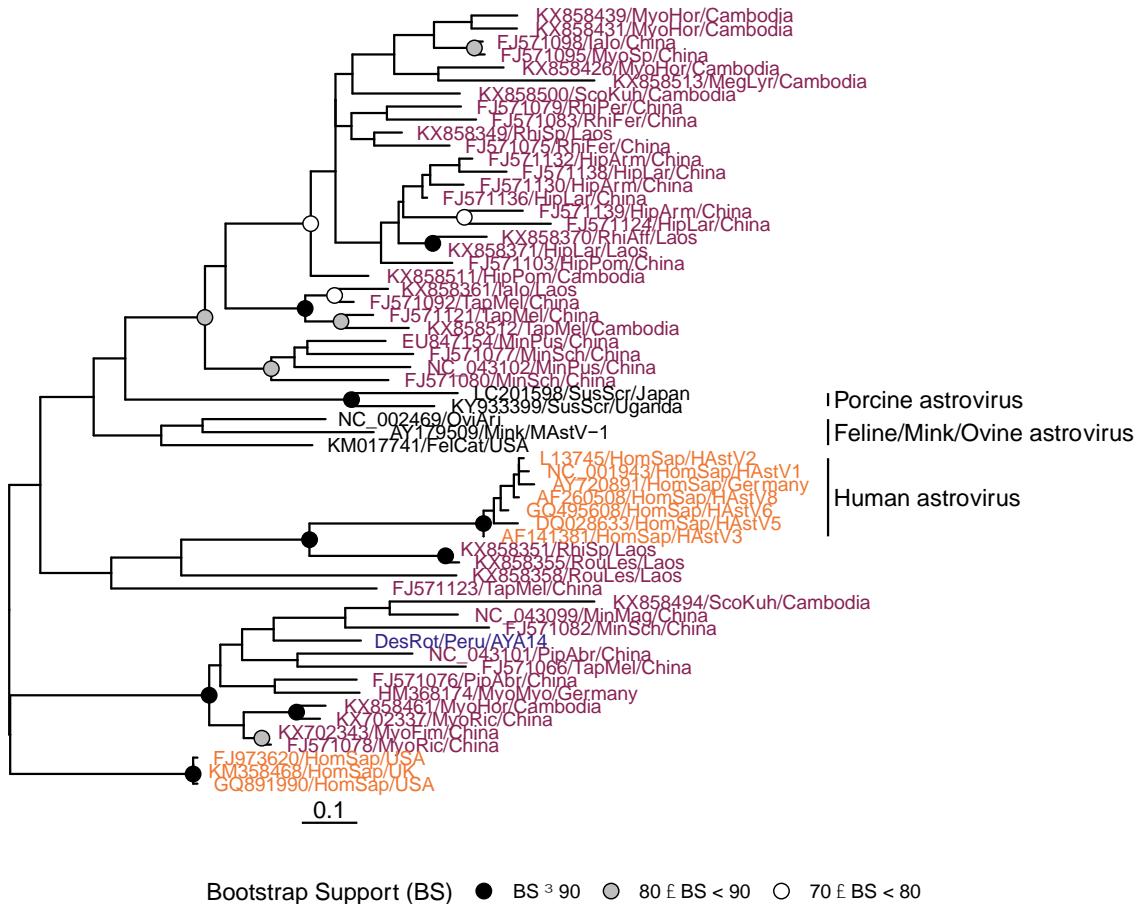

Figure S6. Astroviridae phylogeny. Maximum likelihood phylogeny based on a 128 amino acid alignment of 60 sequences of the RdRp. Phylogenetic analysis was performed in RAxML using the LG+I+G substitution model and 1000 bootstrap replicates. Analyses included one vampire bat-associated AstV sequence (indigo), other bat-associated AstV sequences (purple), human associated sequences (orange) and AstV sequences from non-bat hosts (black). ICTV recognized AstV species are shown on the right. The scale bar represents the mean number of substitutions per site

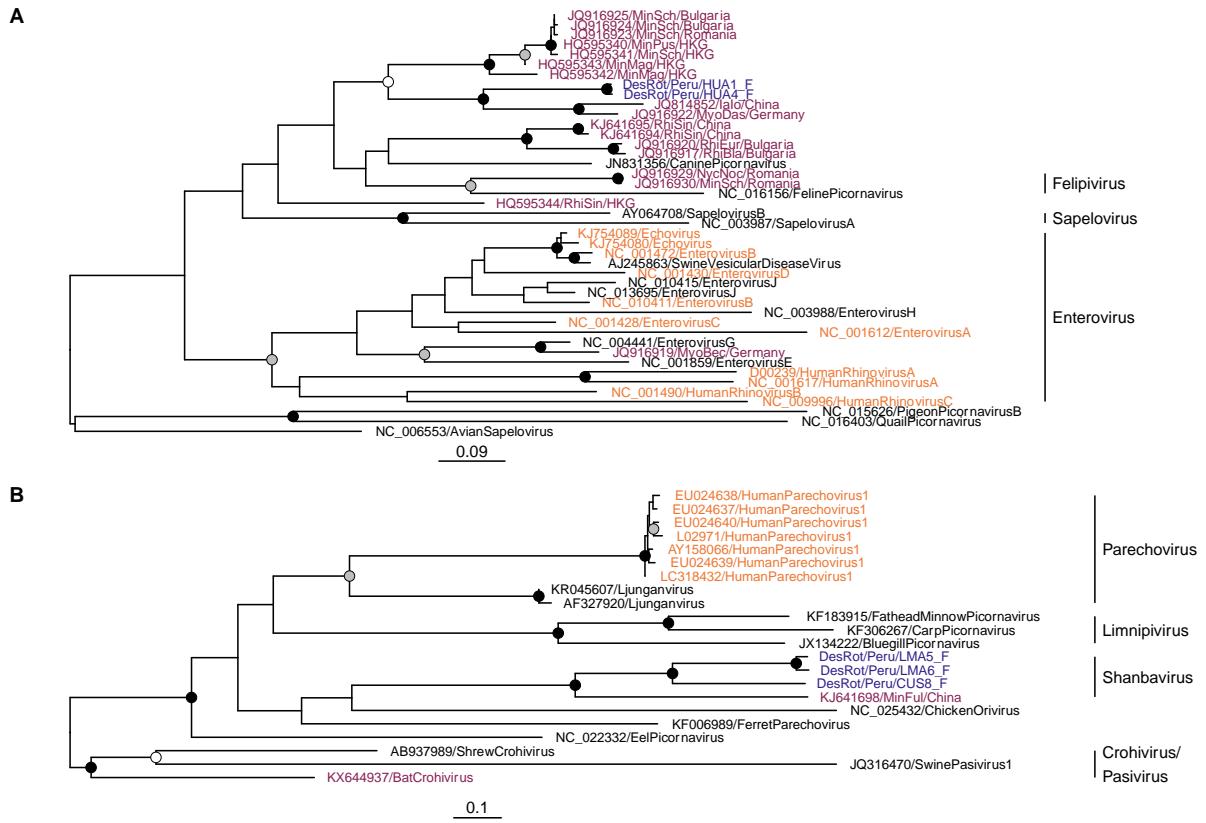

Figure S7. Picornaviridae phylogenies. Maximum likelihood trees of (A) *Enterovirus*-like viruses based on a 265 amino acid alignment of 43 sequences of the 3D polyprotein and (B) *Parechovirus*-like viruses based on a 396 amino acid alignment of 22 sequences of the 3D polyprotein. Phylogenetic analyses were performed in RAxML using the LG+I+G substitution model and 100 bootstrap replicates for both analyses. Colors indicate vampire bat-associated PicoV sequences (indigo), other bat-associated PicoV sequences (purple), human-associated sequences (orange) and PicoV sequences from non-bat hosts (black). ICTV recognized PicoV genera are shown on the right. The scale bars represent the mean number of substitutions per site.

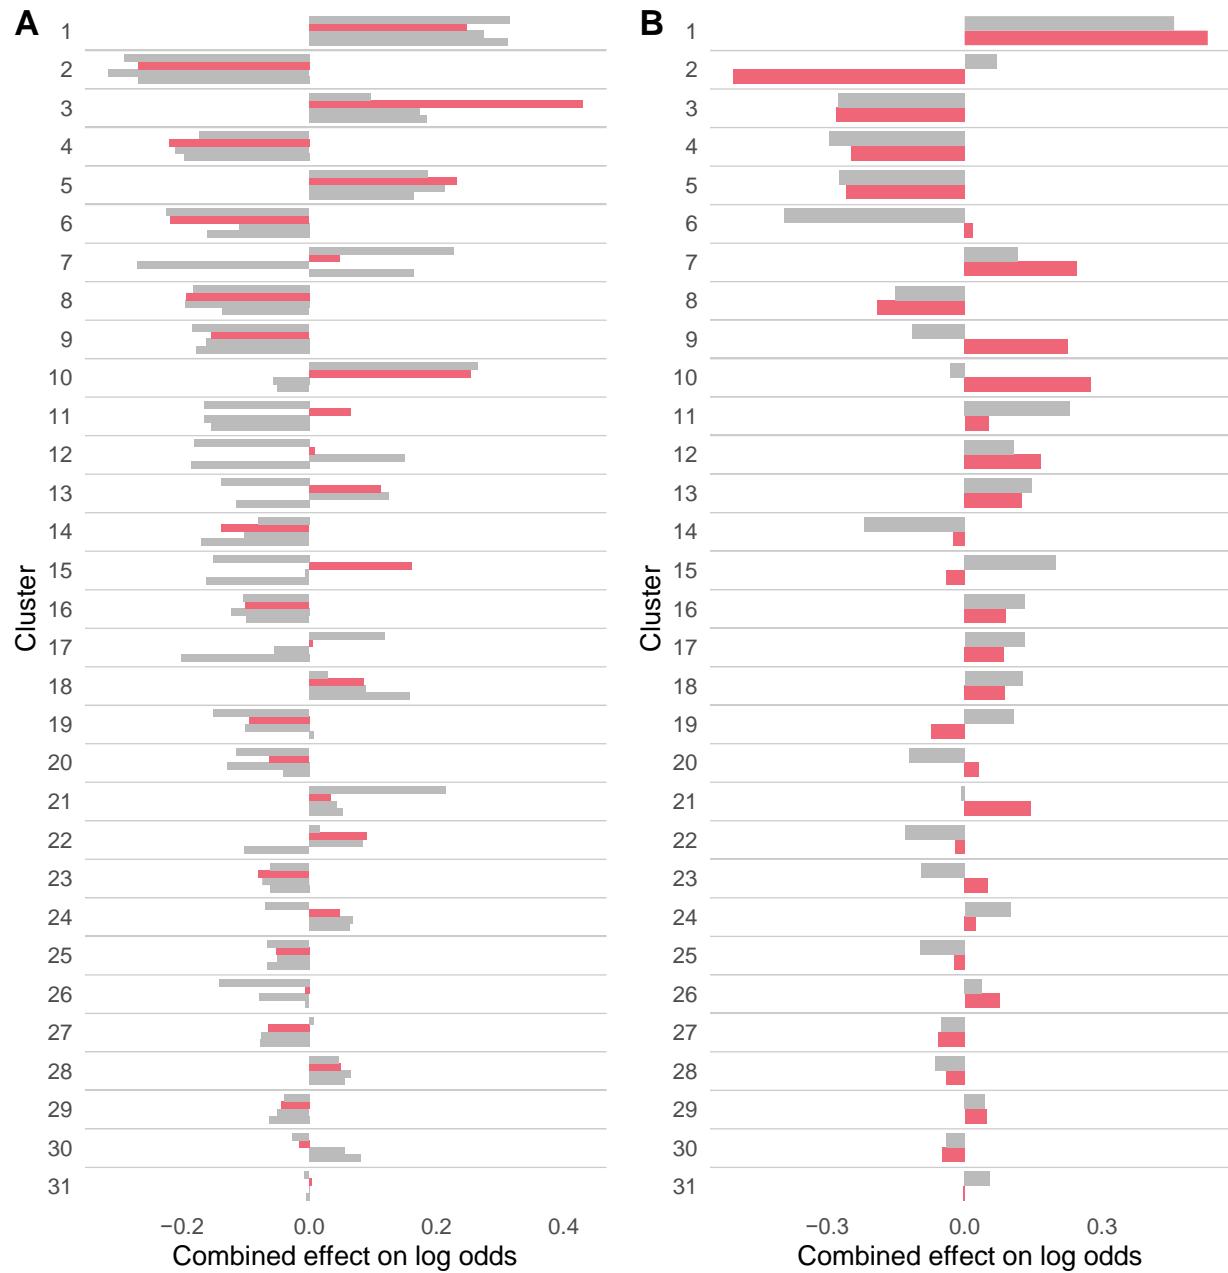

Figure S8. Effect of discrete clusters of correlated features on predicted scores for (A) *Hepeviridae* and (B) *Parechovirus-like Picornaviridae*. In each panel, the highest-ranked virus from that group is highlighted in red (AYA14_F_HEV and CUS8_F_PicoV in panel A and B, respectively). Clusters were taken from Mollentze et al. [15]. The influence of each cluster on the predictions of each virus was calculated by summing effect sizes across all features in the cluster.

Supplementary Tables

Table S1. Metagenomic datasets from which novel vampire bat viruses were characterized.
