Abstract: Supported copper oxide nanoparticles have attracted considerable attention as active and non-precious catalysts for many catalytic oxidation reactions. Herein, mesoporous xCuO-TiO$_2$ nanotube catalysts were fabricated, and their activity and kinetics toward CO oxidation were studied. The morphology and structure of the prepared catalysts were systematically studied using SEM, TEM, EDS, EDX, XRD, TGA, BET, XPS, H$_2$-TPR, and Raman techniques. The BET surface area study revealed the effect of the large surface area of the mesoporous TiO$_2$ nanotubes on promoting the catalytic activity of prepared catalysts. The results also revealed the existence of strong metal-support interactions in the CuO-TiO$_2$ nanotube catalyst, as indicated by the up-shift of the E$_{2g}$ vibrational mode of TiO$_2$ from 144 cm^{-1} to 145 cm^{-1} and the down-shift of the binding energy (BE) of Ti 2p$_{3/2}$ from 458.3 eV to 458.1 eV. The active phase of the catalyst consists of fine CuO nanoparticles dispersed on a mesoporous anatase TiO$_2$ nanotube support. The 50-CuO-TiO$_2$ nanotube catalyst demonstrated the highest catalytic activity with 100% CO conversion at T$_{100}$ = 155 °C and a reaction rate of 36 μmole s^{-1} g^{-1}. Furthermore, the catalyst demonstrated excellent long-term stability with complete CO conversion that was stable for 60 h under a continuous stream. The enhanced catalytic activity is attributed to the interplay at the interface between the active CuO phase and the TiO$_2$ nanotubes support.

Keywords: CO oxidation; copper oxide; mesoporous TiO$_2$; heterogeneous catalysis; metal-support interaction

1. Introduction

The heterogeneous catalytic oxidation of carbon monoxide (CO) is an important reaction for CO removal in many environmental and industrial applications such as air purification, closed-cycle CO$_2$ lasers, the purification of hydrogen from CO traces in polymer electrolyte membrane fuel cell systems [1], and the removal of toxic CO from flue and exhaust gas emissions [2,3]. Precious noble metals such as Ru, Pt, Au, and Pd supported on reducible metal oxides are known for their high catalytic activity for CO oxidation. However, they are expensive and their activity is subject to deactivation, particularly at high temperatures due to the sintering of particles [4]. Therefore, there is a great need to develop non-expensive, active, and durable catalysts for catalytic CO oxidation at low temperatures. TiO$_2$ is an important reducible oxide material that is widely used as a catalyst-support in various heterogeneous catalytic reactions [5–8]. Of particular interest, supported Cu nanoparticles have attracted considerable attention for many catalytic oxidation reactions including CO oxidation owing to their low cost and significant catalytic activity [9–15]. For example, Anil et al. [9] have shown

that Cu-doping increases the catalytic activity of Mn_3O_4 for CO oxidation. Chen et al. [15] have shown that the interaction between Cu and the Ti^{3+} species in rutile TiO_2 can enhance the turnover rate for CO oxidation. Studies have shown that the activation energies for CO oxidation strongly depend on the metal oxidation state, the metal-support interactions, and the amount of oxygen vacancies [13,15,16]. In order to understand the promoting effect of Cu content on the catalytic activity of the TiO_2 nanotubes support, a series of $xCuO$-TiO_2 nanotube catalysts with x = 2–65 wt % were prepared and evaluated for CO oxidation. We demonstrated the influence of CuO modification in the increased metal-support interactions in the CuO-TiO_2 nanotube catalysts, which could increase the catalytic activity for CO conversion due to the synergy between active CuO and TiO_2 entities at the interface.

2. Results and Discussion

2.1. Morphology and Elements Distribution

Titanium dioxide nanotubes with different microstructures and surface morphologies can be synthesized by various techniques such as rapid anodic oxidation [17], template-assisted growth [18], and the hydrothermal method [19]. Of particular interest, the hydrothermal treatment method has received great attention owing to the fairly simple synthesis, low cost processing, chemical versatility, and scalability [19–23]. Figure 1 shows the SEM images of precursor anatase TiO_2 particles (Figure 1a), pristine TiO_2 nanotubes prepared by hydrothermal treatment at 140 °C for 48 h with subsequent acid treatment in diluted HCl aqueous solution to pH 6 (Figure 1b), and the CuO-TiO_2 nanotubes (Figure 1c,d). The TEM images of TiO_2 before and after the CuO modification are shown in Figure 2. The TiO_2 exhibits multi-walled nanotubular morphology with open-ends, an average length of 500 nm, and an average diameter of 10 nm (Figure 2a).

Figure 1. SEM images of (**a**) precursor TiO_2 particles; (**b**) pristine TiO_2 NTs prepared by hydrothermal treatment and (**c**,**d**); CuO-TiO_2 NT catalyst.
Figure 2. TEM images of (**a**) TiO_2 NTs prepared by hydrothermal treatment and (**b**) CuO-TiO_2 NT catalyst.

Figure 3 shows the Energy-dispersive X-ray spectroscopy (EDS) elemental mapping (Figure 3a–e) and elemental analysis (Figure 3f) of CuO-TiO_2 NT catalysts prepared by the hydrothermal method and followed by deposition precipitation. The EDS mapping (Figure 3a–c) reveals that those CuO nanoparticles are highly dispersed on the TiO_2 NT support. The EDX analysis (Figure 3f) indicates a 1:1 at % of Cu:Ti, which confirms the nominal Cu content and the homogenous distribution of the CuO on the TiO_2 NT support. It can also be seen that the Na ratio for the acid treated TiO_2 nanotubes is ca. 0.02. The low Na ratio can be attributed to the replacement of Na^+ with H^+ during the acid rinse [22].

2.2. The Crystal Structure and Thermal Stability

Figure 4a compares the XRD patterns of pristine TiO_2 NTs and 20CuO-TiO_2 NTs with the counterpart CuO and the precursor anatase TiO_2 particles. The diffraction pattern of the TiO_2 NTs exhibits diffraction peaks at 25.3° (101), 38.1° (112), 48.4° (200), 54.1° (105), 55.3° (211), and 62.8° (204), typical of anatase phase as correlated with (Card JCPDS No. 01-071-1166) [24].

For the CuO-TiO_2 NT catalysts, the XRD patterns of the catalysts with CuO content up to 5 wt % do not show diffraction peaks of copper oxide phase and only the anatase phase of TiO_2 is observed

(Figure S1). A similar behavior was reported for CuO-incorporated TiO$_2$ samples with less than 3% Cu species content [25]. The XRD patterns of the CuO-TiO$_2$ NT catalysts with a Cu content larger than 5 wt % (Figure 4a and Figure S1) exhibit diffraction peaks at 35.5° (−111) and 38.6° (111), characteristic of CuO phase in correlation with the reference pattern of tenorite CuO (Card JCPDS No. 00-001-1117) and that reported in the literature for monoclinic phase CuO [26–28]. The strong diffraction peaks of all samples indicate the purity and high crystalline nature of the TiO$_2$ and CuO phases in the different xCuO-TiO$_2$ NT catalysts.

The thermal gravimetric (TGA) graphs of the anatase TiO$_2$, pristine TiO$_2$ NTs, 10CuO-TiO$_2$ NT, and 50CuO-TiO$_2$ NT catalysts are compared in Figure 4b. The TiO$_2$ NTs possessed a weight loss of ~12% upon heating to 600 °C, compared to ~3% weight loss in case of the precursor TiO$_2$ particles. This weight loss in the case of TiO$_2$ NTs is attributed to space shrinkage due to the dehydration of the water located in the interlayer spacing and that adsorbed on the TiO$_2$ NTs surface at temperatures lower than 300 °C, as well as the dehydration of the interlayered OH groups [29,30]. On the other hand, the CuO-TiO$_2$ NTs demonstrated a higher thermal stability compared to the pristine TiO$_2$ NTs support, with a weight loss of about 8% and 4% for the 10CuO-TiO$_2$ NT and 50CuO-TiO$_2$ NT catalysts, respectively. The increased heating tolerance of the TiO$_2$ nanotubes modified with CuO nanoparticles can be attributed to the reduction of the total number of OH groups hydrated in the interlayers of the TiO$_2$ NTs, since Cu is hydrated with fewer OH groups relative to those hydrated at the Ti surface [31].

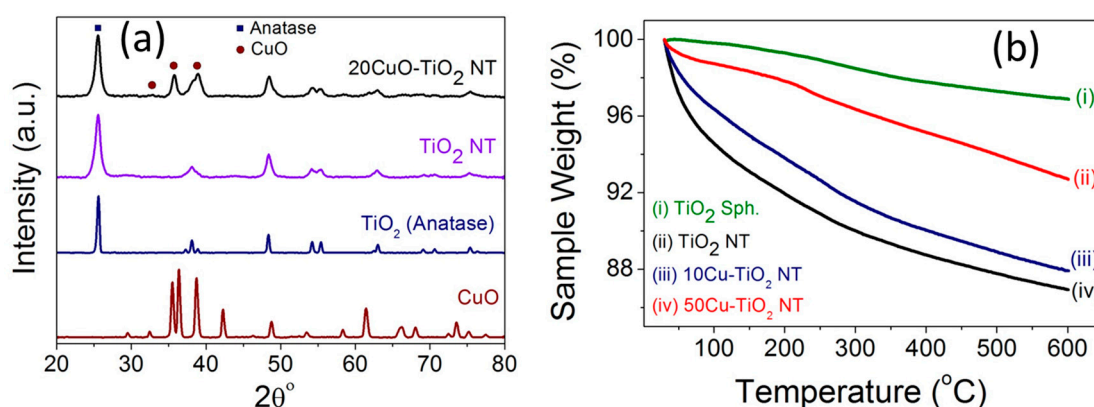

Figure 4. (**a**) XRD patterns of precursor anatase TiO$_2$, pristine TiO$_2$ NTs prepared by hydrothermal method, 20CuO-TiO$_2$ NT, and pure CuO nanoparticles; (**b**) TGA graphs of anatase TiO$_2$, pristine TiO$_2$ NT, 10CuO-TiO$_2$ NT, and 50CuO-TiO$_2$ NT catalysts.

2.3. Surface Properties

Figure 5a–c displays the multipoint BET nitrogen gas adsorption-desorption isotherms of precursor TiO$_2$ particles, pristine TiO$_2$ NTs, and a series of xCuO-TiO$_2$ NT catalysts with different Cu loading (x). Overall, the TiO$_2$ NTs and the different xCuO-TiO$_2$ NT catalysts exhibit type-IV isotherms with a distinct hysteresis loop in the range of 0.65–1.0 relative pressure, typical of mesoporous structured materials [24,32]. The BET surface area of TiO$_2$ increased from 10 m^2/g in the case of the precursor TiO$_2$ spherical particles, to 183 m^2/g for the TiO$_2$ NTs prepared by the hydrothermal treatment at 140 °C for 48 h. This indicates that the tubular morphology enlarged the surface area of the support material due to the contribution from the interstice and the internal space of the TiO$_2$ NTs [22]. The surface area of 183 m^2/g obtained for TiO$_2$ NTs is a little lower than that reported for TiO$_2$ NTs by Nakahira et al. [22], but is similar to the value reported for defective TiO$_2$ (188 m^2/g) by Shah et al. [24]. For xCuO-TiO$_2$ NT catalysts, there is no significant change in the shape of the adsorption-desorption isotherms from that of the pristine TiO$_2$ NTs, but there is a change in the BET surface area. The BET surface area of the different xCuO-TiO$_2$ NT catalysts is lower than that of the pristine TiO$_2$ NTs and the BET surface area decreases when increasing the Cu loading ratio (Figure 5d and Table 1). The decrease

in the BET surface area of TiO_2 NTs upon modification with CuO is attributed to the occupation of the porous features with CuO nanoparticles, in agreement with the literature [28,33]. Unlike the decrease of the BET surface area, there is no significant change in the corresponding average pore size (21–23 nm) when increasing the Cu loading (Table 1). This behavior is in agreement with the literature [28] and indicates that the mesoporous nature of the $xCuO-TiO_2$ NT catalysts did not significantly change, which makes them suitable for various catalytic applications based on their porous structure.

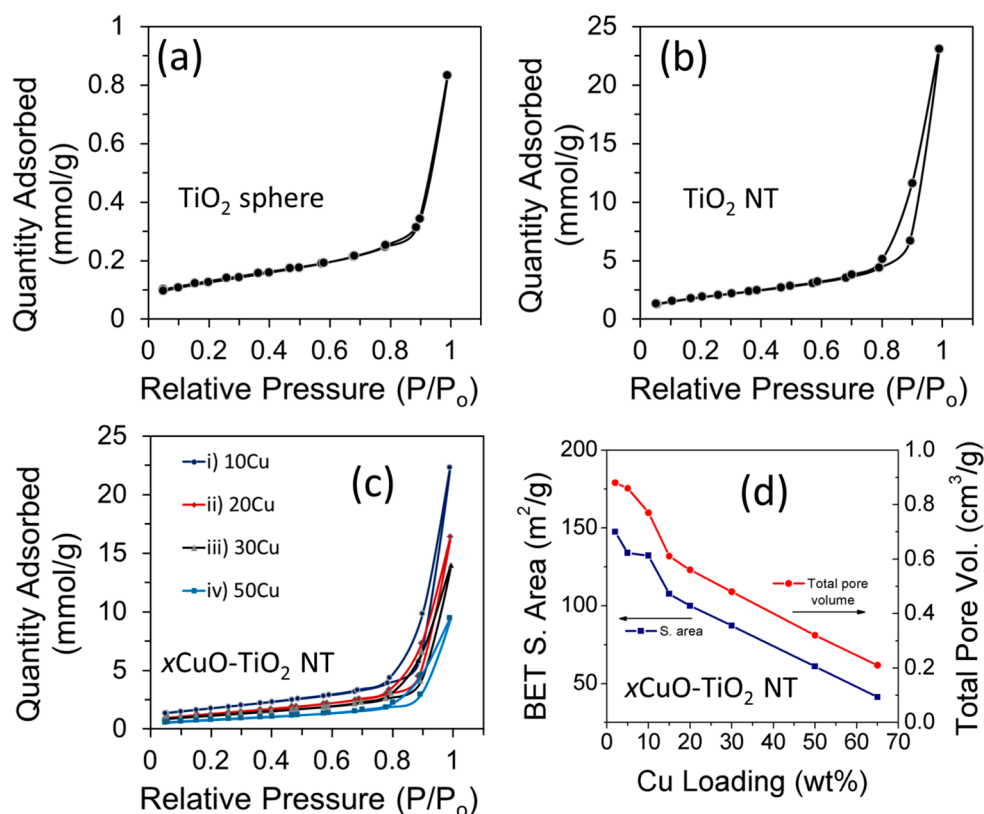

Figure 5. (**a**–**c**) Multipoint BET nitrogen adsorption-desorption isotherms of (**a**) precursor TiO_2 particles; (**b**) pristine TiO_2 NTs; and (**c**) xCuO-TiO_2 NT catalysts with different Cu loading; (**d**) Plot showing variation of the surface area and total pore volume with changing Cu loading of xCuO-TiO_2 NT catalysts.

Table 1. BET surface area, total pore volume, and average pore diameter of different catalysts.

Catalyst	BET Surface Area (m^2/g)	Total Pore Volume (cm^3/g)	Average Pore Width (nm)
CuO	33.5	0.30	35.8
TiO_2 P25	44.8	0.15	12.2
TiO_2 (Anatase)	9.1	0.02	12.6
TiO_2 NT	183.2	0.76	16.7
2CuO-TiO_2 NT	147.5	0.88	23.9
5CuO-TiO_2 NT	133.9	0.86	25.7
10CuO-TiO_2 NT	132.2	0.77	23.4
15CuO-TiO_2 NT	107.6	0.61	22.7
20CuO-TiO_2 NT	99.9	0.56	22.7
30CuO-TiO_2 NT	87.2	0.48	22.2
50CuO-TiO_2 NT	60.95	0.32	21.4
65CuO-TiO_2 NT	41.3	0.21	21.2

2.4. Valence States

X-ray photoelectron spectroscopy (XPS) measurements were carried out to investigate the chemical environment and electronic structure of Ti, O, and Cu in the TiO_2 NTs, CuO nanoparticles, and CuO-TiO_2 NTs catalysts. Figure 6a–c displays the high-resolution XPS spectra of Ti 2p, O 1s. and Cu 2p of TiO_2 NTs and CuO-TiO_2 NTs. The HR-XPS scan for the Ti 2p in TiO_2 was acquired from 450 to 470 eV. For Cu 2p and O 1s, the HR-XPS scan was acquired from 930 to 970 eV and from 520 to 544 eV, respectively. The binding energy values can be used to derive information on the chemical and electronic structure state of Ti cations in TiO_2 [32]. As shown in Figure 6a, the Ti $2p_{3/2}$ peak shifts from 458.3 eV for pristine TiO_2 NTs to 458.1 eV for CuO-TiO_2 NTs, corresponding to a shift of -0.2 eV to a lower binding energy. This shift of the Ti $2p_{3/2}$ peaks is accompanied with another -0.4 eV shift of the Ti $2p_{1/2}$ peak from 464.1 eV to 463.7 eV for pristine TiO_2 NTs and CuO-TiO_2 NTs, respectively. The negative shift of both Ti $2p_{3/2}$ and Ti $2p_{1/2}$ is meaningful of two distinguished TiO_2 entities and suggests the change of electronic structure of TiO_2 in CuO-TiO_2 NTs due to the possible formation of Ti^{3+} species and oxygen vacancies in the support. The binding energies of the Ti 2p peak at 458.1 and 463.7 eV in CuO-TiO_2 aligns well with values reported for Cu-modified TiO_2 [34–37]. Moreover, the negative shift of Ti 2p peaks is in agreement with a similar trend observed for Ti^{3+}-doped TiO_2 with increased oxygen vacancies [32,37,38].

Figure 6b shows the high resolution XPS spectra of O 1s for the pristine TiO_2 and CuO-TiO_2 NTs catalyst. For TiO_2 NTs, an intense O 1s peak centered at 529.6 eV is observed and is attributed to the lattice O^{2-} anions bonding to the metal cations in the Ti-O bond [35,36,39]. For CuO-TiO_2 NTs, the O 1s peak broadens and shifts from 529.6 eV to 529.3 eV. Additionally, a weak shoulder peak is observed at 531.5 eV, which can be attributed to the adsorbed oxygen anions in the (OH–) groups on the surface [35,36] or to the oxygen in CuO [40]. The binding energies of the Cu^{2+} XPS peaks are slightly higher for CuO supported on TiO_2 NTs compared to the unsupported CuO nanoparticles, as shown in Figure 5c. The Cu $2p_{3/2}$ and Cu $2p_{1/2}$ peaks for supported CuO were centered at 933.2 and 953.1 eV, compared to 933 and 952.9 eV in the case of unsupported CuO, respectively. The upshift of the Cu 2p peaks to a higher binding energy for CuO-TiO_2 NTs indicates the strong interaction between the CuO nanoparticles and the TiO_2 NTs support, and is in agreement with the literature [7,25,28,33].

Figure 6d displays the H_2-TPR profiles of CuO and CuO-TiO_2 NT catalysts, comparing the reduction behavior of the unsupported and TiO_2 NT-supported CuO catalysts. Three reduction peaks denoted α, β, and γ—at temperatures lower than 250 °C in the CuO-TiO_2 NT catalyst were observed at 136 °C, 218 °C and 236 °C, respectively, compared to a single reduction peak denoted δ observed at 270 °C for unsupported CuO. The two α and β reduction peaks in the case of CuO-TiO_2 NTs can be attributed to the reduction of the small-sized CuO species finely dispersed on the surface of the TiO_2 NTs support in the form of $Cu^{2+} \rightarrow Cu^+$ and $Cu^+ \rightarrow Cu^0$. The γ reduction peak at a higher temperature can be ascribed to the reduction of the larger sized-CuO nanoparticles interacting deeply with the TiO_2 NTs lattice [41].
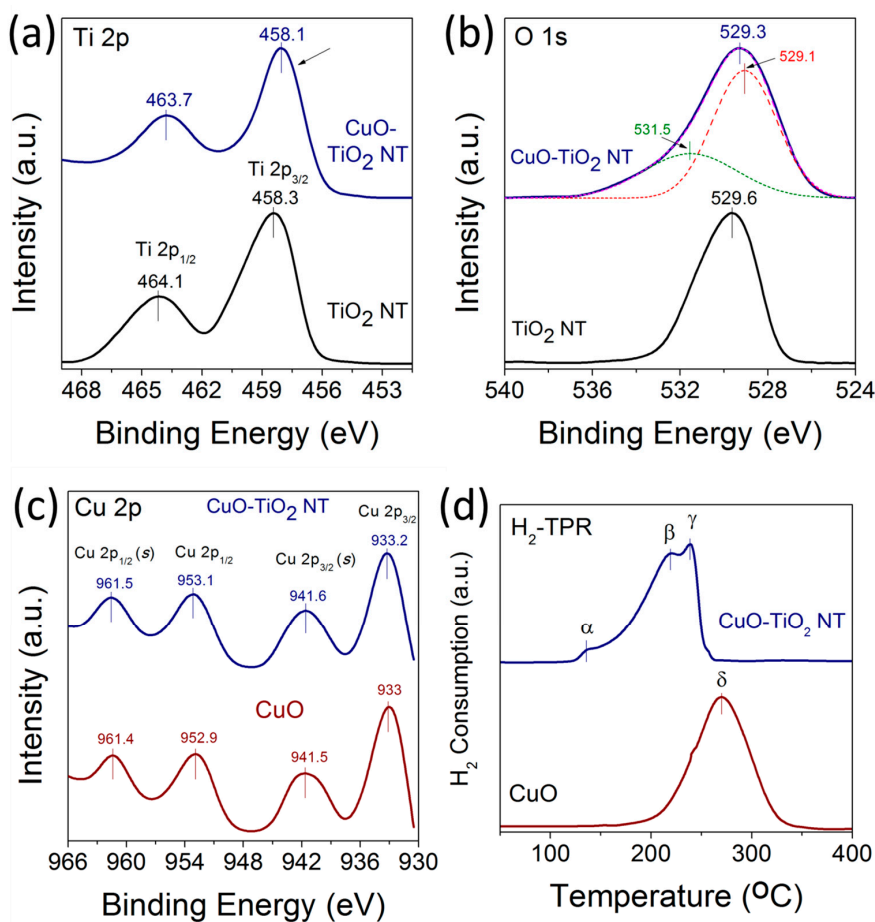

Figure 6. (**a**–**c**) XPS spectra of high-resolution scan of (**a**) Ti 2p; (**b**) O 1s of TiO_2 NT and CuO-TiO_2 NTs; (**c**) Cu 2p of CuO and CuO-TiO_2 NTs; (**d**) H_2-TPR profiles of CuO and CuO-TiO_2 NTs catalyst (peaks: α = 136 °C, β = 218 °C, γ = 236 °C, δ = 270 °C).

2.5. Metal-Support Interactions

Raman scattering analysis was performed to confirm the strong metal-support interaction existing in CuO-TiO_2 NTs and to reveal the structural phases of TiO_2 and CuO. Figure 7a–c shows the full (Figure 7a) and enlarged (Figure 7b,c) Raman spectra of anatase TiO_2, TiO_2 NTs, and CuO-TiO_2 NTs. The tetragonal anatase TiO_2 belongs to the space group D4h with two TiO_2 chemical formula units (six atoms) in each primitive unit cell. Accordingly, there are three infrared active modes and six Raman active modes, namely ($1A_{1g} + 2B_{1g} + 3E_g$) associated with the Ti-O stretching and bending vibration [42–44]. The six allowed vibrational modes in the first-order Raman spectrum of anatase TiO_2 are identified as: (i) three E_g modes associated with the symmetric vibration of O-Ti-O in TiO_2; (ii) two B_{1g} modes due to the symmetric bending vibration of O-Ti-O; and (iii) one A_{1g} mode resulting from the antisymmetric bending vibration of O-Ti-O [43]. The Raman spectrum of the TiO_2 NTs shown in Figure 7a exhibits five pronounced peaks at 140 cm^{-1} (E_g), 194 cm^{-1} (E_g), 393 cm^{-1} (B_{1g}), 514 cm^{-1} ($A_{1g} + B_{1g}$), and 637 cm^{-1} (E_g), in addition to a weak combination broad band at 125 cm^{-1}. The intense E_{2g} peak at 140 cm^{-1}, the two low-intense E_g peaks at 195 cm^{-1} and 637 cm^{-1}, and other broad peaks at 394 cm^{-1} and 510 cm^{-1} corresponding to the B_{1g} and $A_{1g}+B_{1g}$, respectively, confirm the anatase phase of the TiO_2 NTs as reported in the literature [42]. In the case of CuO-TiO_2 NTs, the intense E_{2g} peak associated with the symmetric stretching vibration of O-Ti-O is broadened and shifted to a higher wavenumber along with an increased FWHM line width (Figure 7b) upon CuO modification. The upshift of the E_g mode characteristic to crystalline anatase TiO_2 from 140 cm^{-1} to 145 cm^{-1} in

CuO-TiO$_2$ NTs can be attributed to the presence of oxygen vacancies [24,45,46]. The CuO modification resulted in changes in the structural and vibrational properties of the TiO$_2$ lattice, which indicates the strong interaction between the CuO and TiO$_2$ NTs support [35,46–48]. The position of the Raman peaks associated with the B$_{1g}$ and A$_{1g}$ vibration modes of TiO$_2$ was influenced by the CuO modification in CuO-TiO$_2$ NTs compared to pristine TiO$_2$ NTs, as can be seen in Figure 7b. However, in addition to the scattering peaks which are assigned to the anatase phase of TiO$_2$, another peak centered at 274 cm^{-1} is clearly observed (Figure 7c) and is attributed to the CuO phase [49] which is dispersed on TiO$_2$ NTs (Figure 1c,d and Figure 2b). Because of the negative shift of the XPS peaks of Ti 2p to a lower binding energy and the blue shift of the E$_g$ Raman mode of TiO$_2$, it is reasonable to conclude the slight formation of partially-reduced Ti species (Ti^{4+}) by the free electrons left from the oxygen vacancies formed in the CuO-TiO$_2$ NTs. As can be seen in Figure 6a, it should be noted that the energy difference between the XPS Ti 2p$_{3/2}$ and Ti 2p$_{1/2}$ peaks for the CuO-TiO$_2$ NTs (5.5 eV) is comparable to that of the pristine TiO$_2$ nanotubes (5.4.eV), which confirms that the anatase phase is maintained upon CuO loading [48].

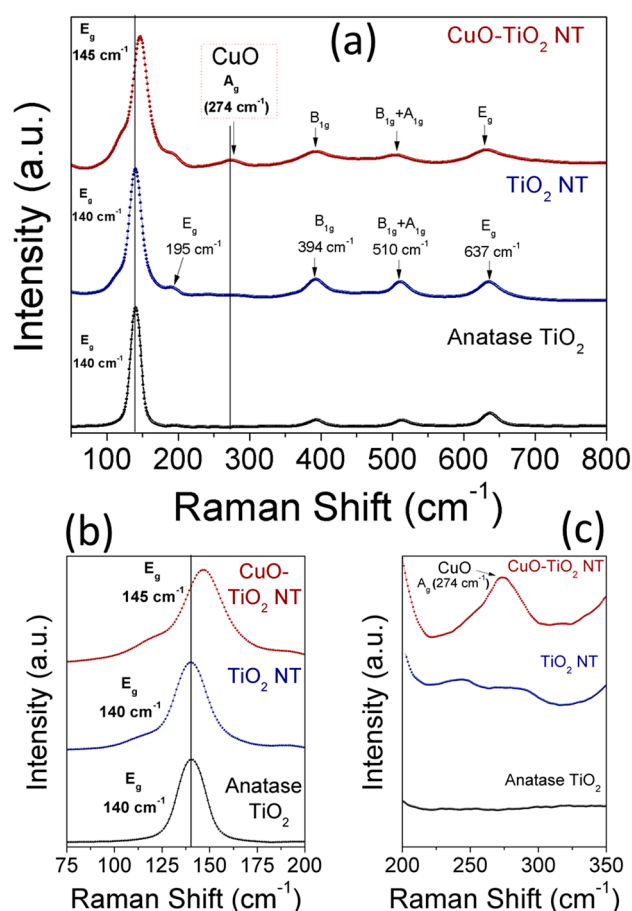

Figure 7. (**a**–**c**) Raman spectra of anatase TiO$_2$ particles, TiO$_2$ NTs, and CuO-TiO$_2$ NTs; (**b**) shows the up-shift of E$_g$ mode of TiO$_2$ from 140 to 145 cm^{-1}; and (**c**) shows the CuO peak at 274 cm^{-1}.

2.6. Catalytic Activity, Stability and Kinetics

2.6.1. Effect of Cu Content on CO Oxidation

The catalytic activity of the different catalysts towards CO oxidation was evaluated using a continuous flow fixed-bed catalytic reactor. Figure 8a,b compares the catalytic activities of TiO$_2$ NTs, CuO, and xCuO-TiO$_2$ NT catalysts with different Cu loading (x = 2–65 wt %) under the feed

gas containing 4% CO and 20% O_2 in a He balance. It is generally accepted that the catalytic activity strongly depends on the composition, size, shape, and dispersion of particles which, in turn, is very sensitive to the procedure of preparation and pre- or post-synthesis treatments [50–52]. As can be seen in Figure 8a, the CO oxidation light-off curve for the CuO nanoparticles only revealed an appreciable activity at temperatures higher than 250 °C and that for the pristine TiO_2 NTs did not reveal significant activity below 400 °C. Therefore, the catalytic activity observed for CO oxidation over CuO-TiO_2 NT catalysts can be ascribed to the interplay between the CuO and TiO_2 counterparts and the strong metal-support interaction at the interface, aligning with the XPS and Raman studies (Figures 6a–c and 7a–c). For the sake of comparison, a 20CuO-TiO_2 (P25) particles catalyst was prepared using the same method and evaluated for CO oxidation under the same experimental conditions. The CO oxidation light-off curve shown in Figure 8a shows that the 20CuO-TiO_2 NT catalyst demonstrated higher catalytic activity for CO oxidation with T_{70} = 146 °C (T_{70} is the temperature corresponding to 70% CO conversion) compared to T_{70} = 166 °C in the case of the 20CuO-TiO_2 (P25) catalyst. The enhanced CO conversion rate at a lower relative temperature can be attributed to the larger surface area of the mesoporous TiO_2 NTs compared to that of TiO_2 P25 (Table 1).

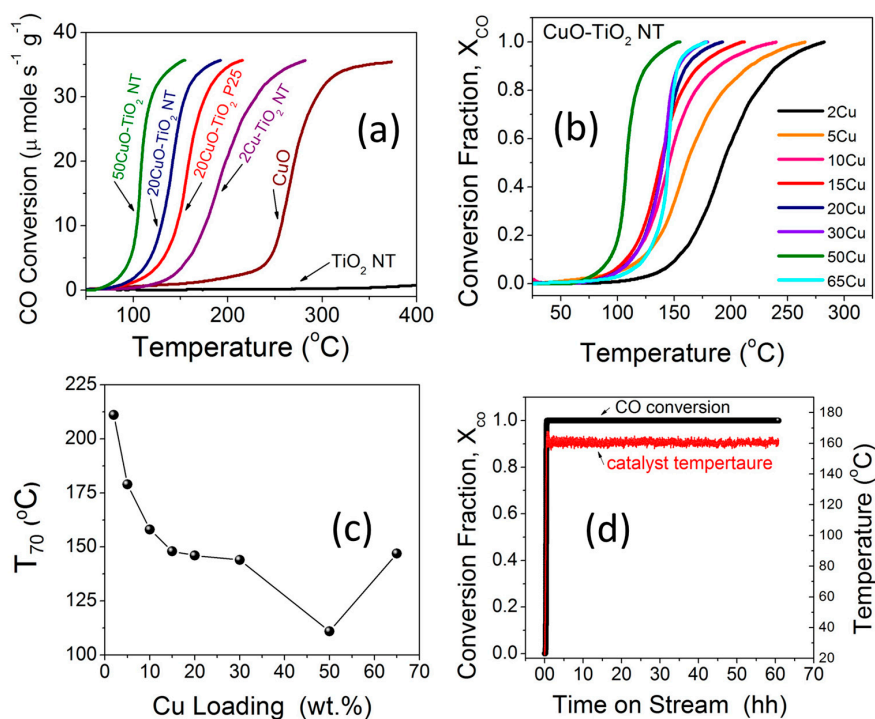

Figure 8. (**a**,**b**) CO oxidation light-off curves of TiO_2 NT, CuO, and different xCuO-TiO_2 NT catalysts; (**c**) Curve showing the variation of the temperature for complete CO conversion (T_{100}) versus CuO loading; (**d**) CO oxidation long-term stability of 50CuO-TiO_2 NT catalyst under continuous stream for 60 h at ~160 ± 5 °C.

When comparing the T_{70} values for different CuO-TiO_2 NT catalysts, it can be seen that the T_{70} decreased from 211 °C to 146 °C when the CuO content is increased from 2 wt % to 20 wt %. The further increase in the CuO content to 50 wt % led to enhanced activity and the T_{70} was further lowered to 111 °C (Figure 8b and Table 2). Overall, the xCuO-TiO_2 NT catalysts with different CuO loading from x = 2–50 wt % demonstrated complete CO conversion at T_{100} values smaller than 250 °C. The light-off temperature for CO conversion decreases remarkably when increasing the CuO ratio in the range from 2 wt % to 20 wt %. The CuO-TiO_2 nanotube catalysts with CuO loading from 20 to 50 wt % yielded slightly undifferentiated CO conversion rates. The 50CuO-TiO_2 NT catalyst demonstrated the highest catalytic activity with 100% CO conversion at T_{100} = 155 °C achieved under a weigh-hourly space

velocity (WHSV) of 72,000 cm^3 g^{-1} h^{-1}, which is 2.4 times larger than that reported in the literature (30,000 cm^3 g^{-1} h^{-1}) [53]. This indicates that larger CO volumes can be converted per unit time per unit weight of the catalyst at a lower residing time. When the CuO ratio is further increased to 65 wt %, the catalyst performance was lowered and the T$_{100}$ increased to 177 °C for 65CuO-TiO$_2$ NT compared to 155 °C for the 50CuO-TiO$_2$ NT catalyst. The lower catalytic activity for the 65CuO-TiO$_2$ NT catalyst might be due to the lower surface area (Tables 1 and 2) or the aggregation of CuO on the TiO$_2$ NTs support. A correlation between the 100% CO conversion temperatures (T$_{100}$) and the CuO loading is presented in Figure 8c. From the catalytic activity measurements (Figure 8b), it can be concluded that the increased CuO promoters increase the strong metal-support interactions and thus results in lower CO conversion temperatures [6]. This strong metal-support interaction arising from the oxygen vacancies in CuO-TiO$_2$ NT catalysts was evidenced from XPS, H$_2$-TPR, and Raman studies, as explained earlier. Compared to other supported plasmonic metal-based catalysts, these CuO-TiO$_2$ NT catalysts exhibit high catalytic activity for CO conversion at a favorable low temperature and can be simply produced at a low cost. Our CuO-TiO$_2$ NT catalysts demonstrated complete CO conversion at a temperature comparable to that reported by Carabineiro et al. [54] for CuO-supported Au catalysts. Furthermore, our CuO-TiO$_2$ NT catalysts exhibited 100% CO conversion at a lower temperature compared to the TiO$_2$-supported Au catalysts reported in the same study [54]. Moreover, comparing our catalysts to Pd catalysts supported on a CeO$_2$-TiO$_2$ mixed oxide [55] and that supported on ZrO$_2$ [56] with a T$_{100}$ value close to 150 °C, the merit of the non-plasmonic CuO-TiO$_2$ NT catalyst with T$_{100}$ = 155 °C is notable given the comparable CO oxidation potency, lower cost, and the long-term thermal stability.

Table 2. The calculated reaction rates, CO conversion at selected temperatures, and the apparent activation energy for different CuO-TiO$_2$ catalysts.

Catalyst	Reaction Rate (μmole s^{-1} g^{-1}) [1]	CO Conversion (%) at T = 155 °C	Temperatures		E$_a$ (kJ mol^{-1}) [2]
			T$_{50}$	T$_{70}$	
2CuO-TiO$_2$ NT	4.3	12	193	211	68.0 ± 3.8
5CuO-TiO$_2$ NT	14	40	161	179	-
10CuO-TiO$_2$ NT	23	66	145	158	-
15CuO-TiO$_2$ NT	28	78	137	148	-
20CuO-TiO$_2$ NT	30	84	139	146	-
20CuO- TiO$_2$ P25	17	46	156	166	79.8 ± 2.4
30CuO-TiO$_2$ NT	32	91	139	144	-
50CuO-TiO$_2$ NT	36	100	108	111	81.0 ±0.7
65CuO-TiO$_2$ NT	33	33	144	147	-

[1] Determined at T = 155 °C; [2] Determined for selected catalysts as indicated with R^2 = 0.99 in each case.

2.6.2. Long-Term Stability

The long-term stability of the 50CuO-TiO$_2$ NT catalyst for CO oxidation was evaluated under a continuous stream of the 4% CO feed gas mixture for 60 h. After the exposure of the catalyst to the feed gas mixture and increasing temperature, a steady state is reached and the 100% CO conversion remains essentially constant after 60 h of operation under a continuous feed gas stream. The high activity demonstrated by the 50CuO-TiO$_2$ NT catalyst at a low-temperature window is not subject to deactivation, as indicated by the stable performance of the of CO conversion for more than 60 h at 160 ± 5 °C (Figure 8d). Moreover, the catalyst maintained the same performance after storage in a closed vial for more than six months in ambient conditions. The CuO-TiO$_2$ NT catalysts could be used as highly stable, efficient, durable, and non-expensive catalysts for CO oxidation at a low temperature window.

2.6.3. Kinetic Studies

Kinetic studies were performed on three selected catalysts, namely 2CuO-TiO$_2$ NT, 20CuO-TiO$_2$ NT, and 50CuO-TiO$_2$ NT, in order to further reveal the effect of Cu content on the catalytic behavior of

the different catalysts. For each catalyst, the effect of varying the temperature and the catalyst loading at a fixed molar gas flow rate was studied. CO oxidation experiments were performed by varying the catalyst loadings as 15, 30, 50, 75, and 100 mg, while keeping the catalysts' bed length and the gas hourly space velocity of the feed gas mixture fixed (3600 $cm^3 h^{-1}$). The CO fractional conversion was calculated from the molar flow of CO at the inlet ($[CO]_{in}$) and outlet ($[CO]_{out}$), as:

$$X_{CO} = \frac{([CO]_{in}) - ([CO]_{out})}{([CO]_{in})} \qquad (1)$$

To collect kinetic data, experiments were carried out under atmospheric pressure and oxygen-rich conditions, at a steady state and in a differential regime (assumed for CO conversion below 0.2). Therefore, the CO oxidation reaction rates (in mol $g^{-1} s^{-1}$) were calculated using the formula:

$$r_{CO} \left(\frac{mol_{CO}}{g_{cat}.min} \right) = \frac{X_{CO}}{(w/F_{CO})} \qquad (2)$$

where (r_{CO}) is the rate of reaction of CO oxidation and w is the weight of the catalyst (in *gram*). The apparent activation energy (E_a) of selected catalysts were determined from the Arrhenius plots ($ln (r_{CO})$ vs. $1/T$) using reaction rate data obtained in the linear region of <20% CO conversion [3,57,58].

Figure 9a–c compares the plots of the CO fractional conversion (X_{CO}) vs. W/F_{CO} at different temperatures in the range of 60–125 °C for the three selected catalysts. In each case, at a fixed W/F_{CO} ratio, a monotonic increase of CO conversion with increasing temperature can be seen, indicating that CO oxidation is enhanced at relatively higher temperatures. The increased CO oxidation can be attributed to the activation of the oxygen adsorbed on the surface of the catalysts, which results in an enhanced diffusion of active oxygen species leading to enhanced CO oxidation rates. This behavior aligns well with the results from the Raman, XPS, and H_2-TPR studies, which indicates the existence of reducible oxygen species on these catalysts at a mid-temperature range. The effect of the contact time in the term of W/F_{CO}, (W = catalyst weight (g) and F_{CO} = molar flow rate ($\mu mol\ s^{-1}$)) on the CO conversion is also presented in Figure 9a–c. For each catalyst at a given temperature, the fractional CO conversion increases when increasing the contact time from to 0.008 to 0.056 g s μmol^{-1} at a fixed gas hourly space velocity (GHSV = 3600 h^{-1}). At the low contact time of 0.008 g s μmol^{-1}, a minimal CO conversion fraction is observed because of the high molar flow rate and the small catalyst weight. This could be due to the relatively lower number of active sites available for the adsorption of reacting gaseous species and thus minimal CO oxidation is observed. When the contact time is increased to 0.016, 0.028, 0.042, and 0.056 g s μmol^{-1} by increasing the catalyst loading mass, sufficient active sites can be realized, leading to increased CO conversion. The CO oxidation reactions present a wide range of kinetic situations with positive- or negative-order reaction rates and a large range of activation energy values [58]. For CuO-TiO_2 mixed-oxide catalysts, a Langmuir-Hinshelwood (L-H) reaction model involving the chemisorption of O_2 on the TiO_2 surface and the chemisorption of CO on the Cu surface and the two chemisorbed species, are reacting at the CuO-TiO_2 interface [59]. Figure 9d–f shows the Arrhenius plots obtained for 2CuO-TiO_2 NT, 20CuO-TiO_2 NT, and 50CuO-TiO_2 NT catalysts under differential reaction conditions, as described in the experimental section. The apparent activation energies (E_a) determined from the Arrhenius plots for the 2CuO-TiO_2 NT, 20CuO-TiO_2 NT, and 50CuO-TiO_2 NT catalysts are presented in Table 2. The order of the apparent activation energy of the three catalysts is: E_a (50CuO-TiO_2 NT) > E_a (20CuO-TiO_2 NT) > E_a (2CuO-TiO_2 NT) catalyst. The order of the calculated CO oxidation reaction rates at 155 °C (Table 2) is: r_{CO} (50CuO-TiO_2 NT) > r_{CO} (20CuO-TiO_2 NT) > r_{CO} (2CuO-TiO_2 NT). The higher activation energy of the 50CuO-TiO_2 NT catalyst might suggest that its catalytic activity is lower than that of the 20CuO-TiO_2 NT or 2CuO-TiO_2 NT catalyst, which contradicts the order of the CO oxidation reaction rates where the 50CuO-TiO_2 NT catalyst demonstrated the highest reaction rate of 36 $\mu mole\ s^{-1}\ g^{-1}$ compared to 30 $\mu mole\ s^{-1}\ g^{-1}$ and 4.8 $\mu mole\ s^{-1}\ g^{-1}$ for the 20CuO-TiO_2 NT and 2CuO-TiO_2 NT catalysts, respectively. However, the experimentally-determined Arrhenius parameters and activation energies represent the apparent

values and the apparent activation energy for a bimolecular catalyzed reaction that does not only depend on the true surface activation energy and the heat of adsorption of the reactants [60]. Therefore, the high values of the apparent activation energies might be due to the strong CO adsorption bond energy to the catalyst surface which increases with increasing Cu loading and is not actually due to a hindered surface reaction, as the order of the apparent activation energy may indicate [61].

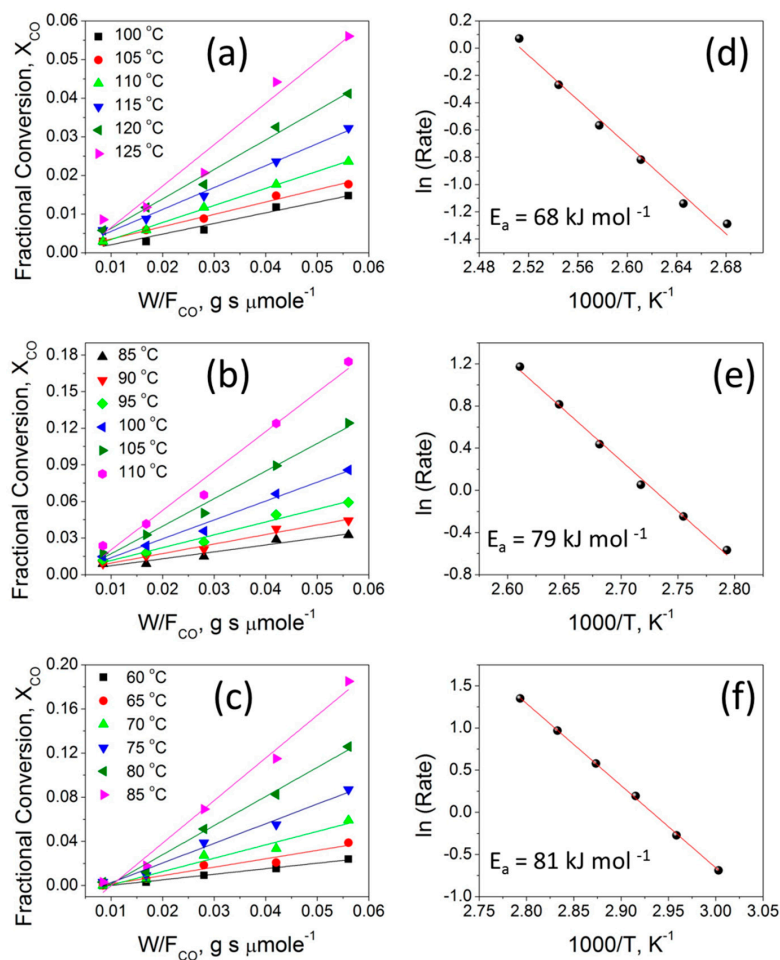

Figure 9. (**a**–**c**) the variation of the CO fractional conversion (X_{CO}) with W/F_{CO} ratio; (**d**–**f**) Arrhenius plots for the 2CuO-TiO$_2$ NT, 20CuO-TiO$_2$ NT, and 50CuO-TiO$_2$ NT catalysts, respectively.

Based on the spectroscopic results and the performance of the catalysts, it can be concluded that the modification of the mesoporous anatase TiO$_2$ NTs with CuO nanoparticles could influence the nature of the defects in the CuO-TiO$_2$ NT catalysts. This led to a strong electronic interaction between the CuO and anatase TiO$_2$ NTs and enhanced catalytic activity [15,16]. In summary, the CuO supported on TiO$_2$ NTs is more active than that supported on commercial TiO$_2$ (P25) particles, indicating the role of the high surface area in promoting the catalytic activity. The activity of CuO-TiO$_2$ NT catalysts can be controlled by changing the Cu:Ti ratio which affects the extent of the metal-support interaction in the mixed oxide catalyst.

3. Materials and Methods

3.1. Materials

Chemicals and reagents were purchased from Sigma-Aldrich (Taufkirchen, Germany) and used without further purification, including titanium (IV) oxide (anatase powder, −325 mesh, ≥99%

trace metals basis, Sigma-Aldrich), sodium hydroxide (reagent grade, $\geq$98%, pellets, anhydrous, Sigma-Aldrich), hydrochloric acid (ACS reagent, 37% deionized water, Sigma-Aldrich), copper (II) nitrate trihydrate (purum, 98%, Sigma-Aldrich), sodium carbonate (ACS reagent, anhydrous, 99.95%, Sigma-Aldrich).

3.2. Methods

3.2.1. Synthesis of TiO_2 Nanotubes Support

The TiO_2 nanotube support (TiO_2 NT) was prepared by the hydrothermal treatment of anatase TiO_2 powder in concentrated aqueous NaOH solution followed by acid treatment in HCl solution [19,21,22,62]. In a typical synthesis, 2 g of commercial anatase TiO_2 particles was added to 40 mL of 10 M NaOH aqueous solution in a 100 mL Teflon vessel. The mixture was stirred for 30 min and then the Teflon-lined stainless steel autoclave was placed in an electric oven (Isotemp, Model 282A, Fisher Scientific, Marietta, OH, USA) and kept at 140 °C for 48 h. After the hydrothermal treatment, the products were separated by filtration and rinsed three times with DI water. Then, the products were soaked in an aqueous solution for 2 h at room temperature after adjusting the pH to 6 with 0.1 M HCl. Finally, the products were separated by filtration and dried in an oven at 80 °C overnight. Dried samples were calcined at 450 °C for 2 h with a heating rate of 2° min^{-1}.

3.2.2. Synthesis of CuO-TiO_2 NT Catalysts

The different CuO-TiO_2 NT catalysts were synthesized by the DP method at ambient conditions of temperature. Precipitates of xCuO-TiO_2 NT catalysts with various Cu loading in the range of x = 2–65 wt % were generally prepared by mixing an aqueous suspension of TiO_2 nanotubes with a predetermined volume of aqueous $Cu(NO_3)_2 \cdot 3H_2O$ solution, followed by the addition of the precipitating agent solution (0.2 m/L Na_2CO_3) at constant pH. In a typical synthesis, a 100 mg TiO_2 nanotube powder was suspended in 100 mL DI water and the suspension was sonicated for 10 min. Then, a pre-determined volume of $Cu(NO_3)_2 \cdot 3H_2O$ aqueous solution with the desired Cu content was added to the TiO_2 NTs suspension and the mixture was sonicated for 10 min, followed by stirring at room temperature for 2 h. Following this, an appropriate volume of 0.2 mole/L Na_2CO_3 aqueous solution was added dropwise to the above suspension, until the pH of the suspension reached ca. 9. The reaction mixture was finally aged under stirring for another 5 h. Upon completion, the resulting precipitate was separated by centrifuge, washed three times with DI water, and dried at 80 °C in an electric oven overnight. The dried powder was calcined in a closed muffle furnace at 450 °C for 2 h with a ramp rate of 2 °C min^{-1}. For the sake of comparison with xCuO-TiO_2 NT catalysts, CuO nanoparticles unsupported and supported on commercial TiO_2 (P25) particles were prepared using the same method.

3.2.3. Catalysts Characterization

The different catalysts were characterized with a toolbox of physical techniques. Transmission electron microscopy (TEM) images were acquired using TECNAI G2 F20 S-TWIN transmission electron microscope (FEI, Brno, Czech Republic) with an accelerated voltage of 200 kV. Powder samples for TEM were dispersed in ethanol by ultrasonication and a droplet of the colloid suspension was dipped onto a Formvar carbon-coated 200-mesh copper grid (Ted Pella) and finally allowed to dry in air at room temperature. Scanning electron microscopy (SEM) images and energy dispersive X-ray spectroscopy (EDX) measurements were carried out using NOVA NANOSEM 450 scanning electron microscope (FEI, Brno, Czech Republic). The powder was sputter coated with gold prior to the SEM analysis, whenever needed. The powder X-ray diffraction (XRD) measurements were carried out at room temperature using a Rigaku MiniFlex II powder diffraction system (Rigaku, Tokyo, Japan) with Cu KαR radiation at 30 kV and 20 mA between 2θ angles of 5° and 80° with a scanning rate of 0.025° per step per second. Nitrogen adsorption and desorption isotherms of

different samples were obtained at 77 K using a Micrometics instrument ASAP 2420 pore size analyzer (Norcross, GA, USA) in the range of 0.05 to 1 relative pressure (P/P_O). The specific surface area was derived using the BET (Brunauer-Emmett-Teller) method, and the pore size distribution and average pore size were estimated from the adsorption branch using the BJH (Barret-Joyner-Halenda) method. Prior to analysis measurement, all samples were degassed in an N_2-He mixture at 90 °C for 1 h and at 150 °C for an additional 1 h. Thermal analysis was conducted using a Perkin Elmer thermal gravimetric analyzer (Pyris 6 TGA) (Groningen, Netherlands) from 50 °C to 600 °C in air at a linear heating rate of 10 °C min^{-1}. X-ray photoelectron spectroscopy (XPS) measurements were carried out on a KRATOS AXIS Ultra XPS with a monochromatic Al Kα radiation source (1486.6 eV) in a UHV environment (ca. 5×10^{-9} Torr) (KRATOS Analytical, Manchester, UK). The operating conditions were kept at constant high resolution pass energy of 20 eV, emission current of 10 mA, and anode HT of 15 kV. In order to subtract the surface charging effect, the C1s peak at 284.8 eV was used for calibration. Temperature-programmed reduction (H_2-TPR) analysis was carried out using a Micromeritics Chemisorb 2750 instrument with ChemiSoft TPx Option (Norcross, GA, USA) equipped with a built-in thermal conductivity detector (TCD) to detect H_2 consumption. For each analysis, 50 mg of the calcined catalyst was heated from ambient temperature to 600 °C, with a heating rate of 10 °C min^{-1} under 10% H_2/Ar balance at a flow rate of 30 mL min^{-1}. Raman spectra were recorded using a DXR 2 Raman Microscope (Thermo Fisher Scientific, Madison, WI, USA) equipped with a 780 nm LASER source for excitation. The spectrum acquisition consisted of 20 accumulations with a total acquisition time of 5 min at a spectral resolution of 4 cm^{-1} and laser power of 5 mW.

3.2.4. Catalytic Activity, Stability and Kinetics Measurements

Catalytic CO oxidation experiments were performed to determine the activity of the catalysts. Experiments were performed using a custom-built continuous flow fixed-bed catalytic test reactor, as depicted in Figure 10. The reactor was equipped with a quartz tube with an inner diameter of 10 mm, which was placed in the middle of a programmable split tube furnace (Lindberg/Blue M Mini-Mite Tube Furnace-Thermo). In all experiments, 50 mg of the test catalyst powder was charged into a bed of quartz wool in the middle area of the quartz tube. The catalyst temperature was measured by a k-type thermocouple placed in contact with the catalyst bed. The reaction gas feed mixture consisted of 4% CO and 20% O_2 in a balance of He and was passed through the catalyst bed (50 mg) at a flow rate of 60 cm^3/min (72,000 cm^3 g^{-1} h^{-1} WHSV). The flow rate was controlled by a set of digital mass flow controllers (HI-TEC, Model-F-201CV-10K-AGD-22-V, Multi-Bus, DMFC; Bronkhorst). All experiments were carried out at atmospheric pressure (1 atm) in the temperature range of 30 to 400 °C, with a ramp rate of 5 °C min^{-1}. The signal from the thermocouple was acquired using a USB-6008 Multifunction I/O and NI-DAQmx (National Instruments) data acquisition board. The effluent gas was fed into an inline multichannel infrared gas analyzer (IR200, Yokogawa, Japan) to analyze the exit gas and simultaneously monitor the CO conversion. The volume percent of the CO, CO_2, and O_2 gases was determined simultaneously and logged, along with the catalyst temperature during the course of the experiment using custom-configured LabVIEW data acquisition software (LabVIEW 2014, Version 14.0F1, National Instruments, Austin, TX, USA). The long-term stability of the selected catalyst was studied at a temperature of 160 ± 5 °C for 60 h under a continuous stream of feed gas. The catalytic activity was expressed by the conversion of CO in the effluent gas and indicated as CO fractional conversion.
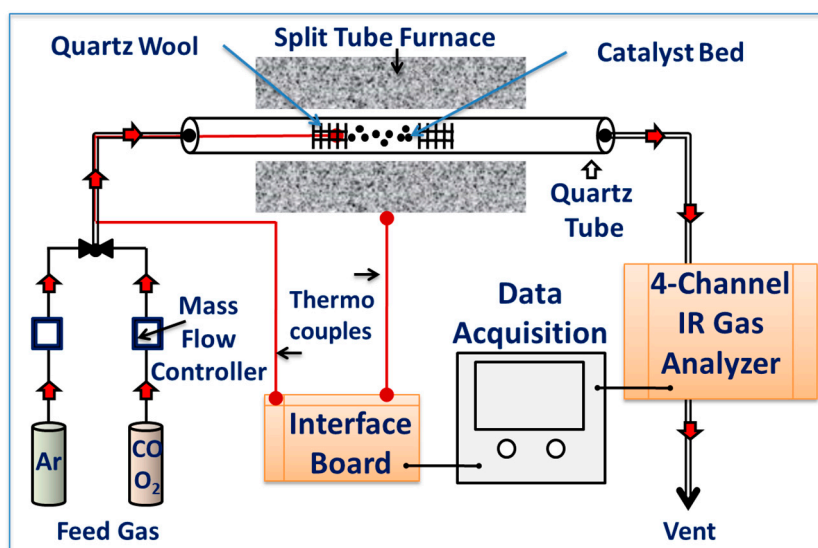

Figure 10. Schematic representation of the catalytic CO oxidation experimental set-up.

4. Conclusions

In summary, readily available active oxygen species are of fundamental importance for strong metal-support interactions and high catalytic activity. In this study, a series of efficient and non-precious mesoporous CuO-TiO_2 NT catalysts with enhanced defects were developed and tested for CO oxidation at low temperatures. The existence of strong metal-support interactions between the Cu and TiO_2 NTs was evidenced by a combination of catalytic activity measurements, including XPS, Raman, and TPR analysis. Raman and XPS studies illustrated the presence of oxygen vacancies in the CuO-TiO_2 NT catalysts, as indicated by the up-shift of the E_{2g} mode of TiO_2 and the down-shift of the binding energy of Ti $2p_{3/2}$ from the Raman and XPS studies, respectively. The CuO-TiO_2 NT catalyst demonstrated low-temperature activity and high stability for CO conversion. The CO conversion rate of the CuO-TiO_2 NT catalysts is greatly enhanced compared to their individual counterparts and a 100% CO conversion is achieved at a low working temperature of 155 °C, with a reaction rate of 36 μmole s^{-1} g^{-1} and an apparent activation energy of 81 ± 0.7 kJ $mole^{-1}$. Furthermore, the performance of the catalysts was stable for 60 h under a continuous stream, without catalyst deterioration or a decrease in the CO conversion ratio.
