**Figure S1.** FT-IR spectra before and after the UV aging test of a) MMA\_POMA, b) MMA\_nBuMA\_POMA and c) EMA\_nBuMA\_POMA samples.

Figure S1 reports a correlation between FT-IR spectra of POMA-based samples before and after the UV aging test. The peak (i) in the  $\sim 3100\text{-}2800\text{ cm}^{-1}$  range is related to the bending of C-H aliphatic bonds; the stretching of carbonyl ester groups (C=O) (ii) appears between  $\sim 1750\text{-}1600\text{ cm}^{-1}$  and the characteristic absorption band for the symmetric stretching vibration of C-O conjugated to carbonyl ester groups (iii) lies in the range  $\sim 1350\text{-}1100\text{ cm}^{-1}$ . In the case of MMA\_POMA resin subjected to UV aging, the shape of the three absorption peaks considered as reference remains unchanged; on the other hand, for nBuMA-based aged resins, it is possible to observe a small change in terms of peaks intensity in the area between 1350 and 1100  $\text{cm}^{-1}$ , related to the breaking of carbonyl ester bonds.

**Figure S2.** <sup>1</sup>H NMR and FT-IR spectra of a) MMA\_POMA and b) MMA\_nBuMA\_POMA resins removed from stone substrates.

Figure S2 shows MMA\_POMA and MMA\_nBUMA\_POMA a) <sup>1</sup>H NMR spectra and b) FT-IR curves collected after removal. From the comparing of unaged (Figure 3 and S1) and aged macromolecular and chemical structures, it is worth of note the absence of significant differences in terms of chemical bonds and peaks intensity change of the resulting polymers.
