**Abstract:** The extent of failure evaluation depends on the complexity and significance of electronic products. However, traditional failure mode and effect analysis (FMEA) has many shortcomings, which brings large difficulty to failure evaluating work. This paper uses the double hierarchy hesitant fuzzy linguistic term set (DHHFLTS) and the K-means clustering algorithm to improve the shortcomings of traditional FMEA. The DHHFLTS is a set of language terms based on the symmetry method and uniform language granularity. Firstly, we determine the product failure mode and set up an evaluation team after formulating an evaluation symmetrical language set. The psychological changes of the evaluators can be truly expressed by using the DHHFLTS. Secondly, the entropy weight method is used to calculate the weight of the evaluation members. The evaluation information of the evaluation personnel on the failure mode is aggregated based on the weight of the evaluation members. Then, the K-means clustering algorithm is used to calculate the distance between failure modes and each cluster center point by using the normalized weight of influencing factors and the evaluation distance of each evaluator. Finally, the evaluation of an electromagnet failure mode is taken as an example to prove the objectivity and practicability of the new method.

## 1. Introduction

With the increasing competition for electronic products, people's consumption ideas are becoming pragmatic, and quality and reliability have become the main factors for products to occupy the market share. The failure evaluation quality of the judges directly affects the working performance of electronic products. An accurate and comprehensive failure evaluation has proven to be the best measure of success for product design and development. Thus, in order to achieve the goal of improving the quality and reliability of products, the first important measure for identifying and sorting the potential failure modes is the correct prevention and optimization method. Most importantly, many evaluation methods and their tools provide instant feedback so that we can react in real time to the quality parameters of electronic products. At present, the research on reliability analysis has produced a lot of achievements. Zhang et al. [1] proposed a reliability model based on the Bayesian network and Marshall–Olkin Weibull distribution to analyze the reliability of product dynamics. These research results provide new ideas for the research of reliability analysis, but these methods are not suitable for the actual use of enterprises because of their large amount of data processing and complex calculation [2].

As a common method of reliability analysis, FMEA is widely used in the design and production stage of various products, such as offshore wind turbines [3], furniture manufacturing [4], semiconductor design [5], and other industries. FMEA identifies all potential failure modes by analyzing the subsystems and parts that make up the product and each step of the product's design process. It is a systematic activity to analyze its

possible consequences and take necessary measures in advance to improve the quality and reliability of products [6]. Compared with other reliability analysis methods, the calculation process is simple and suitable for the actual production process of enterprises [7]. With the increase in FMEA frequency and scene, its own problems are also exposed. Firstly, the FMEA evaluation process uses accurate numbers to evaluate the failure mode, which does not conform to people's language habits when evaluating. Secondly, the weight of the influencing factors in the FMEA evaluation is equally divided, without considering the relative importance of the influencing factors. In addition, the weight of the evaluation members is also subjectively specified, which will lead to unreal evaluation results. Thirdly, the risk priority number (RPN) is used to sort the final results. RPN includes severity (S), occurrence (O), and detection (D), which will lead to the same RPN value, and the values of each influencing factor may be different. However, for enterprises, compared with the failure mode with high frequency and a low detection degree, the failure mode with high severity needs more preventive measures in advance, so traditional FMEA cannot guide the production of enterprises well.

In view of the shortcomings of traditional FMEA, many scholars have made improvements. On the one hand, intuitionistic fuzzy sets (IFSs) can replace accurate numbers in the evaluation language and better express people's fuzzy psychology in the evaluation process. Chang et al. [8] used IFSs to evaluate the reliability of an octane system and to some extent improve the evaluation language, but IFSs can only describe the members' fuzzy psychology. They cannot express the hesitation of evaluation members; for example, some evaluators believe that the severity should be between high and high language sets, which is impossible to express for the IFS. The rest, such as trapezoidal [9] and triangular fuzzy numbers [10], can only express ambiguity, but they cannot express hesitation very well. Relative to fuzzy linguistic sets (FLSs), hesitation fuzzy linguistic sets (HFLSs) can not only express the fuzziness of evaluation, but also the hesitation of evaluation. Zhang et al. [11] used probabilistic interval-valued hesitant fuzzy sets (PIV-HFSs) to express the evaluation information of evaluation members, and using interval-valued fuzzy sets can include the real thoughts of evaluation members. Liu et al. [12] added two-tuple semantics to an HFLS. When they were used to process the HFLS for integration, the integration results exceeded the linguistic terms set, and language information was lost. In addition, triangular hesitant fuzzy sets [13], hesitant Z-numbers [14], and intermediate two-tuple fuzzy sets [15] can express the hesitant mentality of the evaluators, which is particularly important for reliability analysis in the context of dynamic production [16]. However, these methods are very large for the partition interval of language sets and cannot express sentences that are a little higher. In addition, more data are needed to express language sets, such as triangular hesitant fuzzy numbers, which need  $a$ ,  $b$ , and  $c$  data to determine triangular fuzzy numbers. The DHHFLTS is composed of double hierarchy linguistic term sets (DHLLTSs) and HFLTSs. It divides the first hierarchy linguistic set by using the second hierarchy linguistic set to shorten the interval length of the linguistic set. Its double hierarchy language set is based on the concept of symmetry, so it can really depict bipolar psychology during the evaluation process. The final evaluation information is to select a limited and orderly continuous linguistic term set from the DHHFLTS to form a hesitant interval [17]. So far, based on the existing FMEA evaluation forms and research background, this paper holds that the DHHFLTS can concisely express the complex psychology of the evaluator [18].

On the other hand, there are many ways to confirm the influencing factors and the weight of evaluation members in many research fields. Pang et al. [19] used the similarity measure method to calculate the distance between evaluation information and its center point, normalized it to obtain the weight of evaluation members, and constructed a nonlinear programming model to solve the weight of influencing factors according to the pairwise comparison matrix of influencing factors. Boral et al. [20] used the fuzzy analytic hierarchy process (FAHP) and modified fuzzy multi-attribute ideal real comparative analysis (modified FMAIRCA) to calculate the fuzzy relative importance among the influencing

factors so as to obtain the weight of the influencing factors. Tian et al. [21] used fuzzy best-worst and relative entropy methods to calculate the weight of influencing factors and evaluation members. Firstly, the fuzzy best difference of the interval evaluation value of influencing factors was calculated to obtain the weight of influencing factors. Then, based on fuzzy proximity and fuzzy similarity entropy methods, the fuzzy distance between the evaluation method of each evaluation member and the central scheme was calculated to obtain the weight of FMEA team members. In addition, the entropy weight method [22], fuzzy metric [23], the multi-objective optimization model [24], and other methods can calculate the influencing factors and evaluate the weight of members. However, by observing these methods, it is found that it is quite common to find the evaluation information center point and calculate the distance between the evaluation information and the center point to obtain the weight information. Therefore, when choosing the weight solution method, it should be close to the mainstream idea and simple calculation process. The K-means clustering algorithm determines the center point of each clutter through calculation and calculates the distance between each evaluation information and the center point by using the weight. The calculation process is simple, and it can also avoid the situation that the evaluation result is not true due to the large gap in evaluation information [25]. Therefore, this paper is based on the K-means clustering algorithm and entropy weight method to solve the influencing factors and evaluate the weight of members.

The K-means clustering algorithm was first proposed in 1967 and has been widely studied and applied in different disciplines. It has the advantages of simplicity, high efficiency, and is suitable for dealing with large data sets. It is the most widely used and mature clustering analysis method so far [26]. It is widely used in data processing [27], image processing [28], market analysis [29], and many other research fields [30]. The K-average clustering algorithm is the core thought in the center of the data set to choose K-class data clustering and the clustering center according to the calculated attribute value, and the value of the minimum Euclidean distance principle can be divided into K classes. The average of each category data is calculated as a new clustering center for the next iteration until the clustering center is no longer changed. The value of each cluster center is redivided and updated successively until the optimal clustering result is obtained [31]. Clustering the evaluation information of failure modes can find the central point around the evaluation process of all evaluation members. Then, by calculating the distance between the evaluation information and the final center point, it is easy to obtain the weight of the influencing factors. Compared with other weight calculation methods, the K-means clustering algorithm is simpler, and the data needed for solving are all from the data collected, so the results are more reliable [32]. As mentioned above, the K-means clustering algorithm is an iterative clustering analysis algorithm. Compared with other weight-solving methods, it can not only calculate the weight based on current failure modes, but also predict the weight of influencing factors of future failure modes [33]. Since the DHHFLTS sets language granularity based on symmetric concepts, it may lead to a large gap in evaluation information among evaluators by using the DHHFLTS. Furthermore, the K-means clustering algorithm can reduce the gap between the evaluating variables.

The rest of this paper is organized as follows. In Section 2, we introduce the definition and calculation rules of the DHHFLTS. In Section 3, we introduce the calculation flow of the K-means clustering algorithm and the calculation idea of the entropy weight method combined with the cluster center to solve the influencing factors with the weight of the evaluators. In Section 4, we expound on the whole context of the new method. An example of an electromagnet is used to prove the objectivity and applicability of the method, and the final calculation results are analyzed in Section 5. In Section 6, we summarize the advantages of the proposed new method in the context of work and point out future research directions.

## 2. Double Hierarchy Hesitant Fuzzy Linguistic Term Set

According to classical theory, the DHHFLTS is composed of DHLTSs and HFLTSs. Therefore, it can not only express complex semantics like the DHLTS, but also express fuzzy and hesitant semantics like the HFLTSs [34]. In this part, we introduce the definition, form and calculation rules of the DHLTSs, HFLTSs and DHHFLTSs in turn.

### 2.1. Double Hierarchy Linguistic Term Set

As in our daily life, when we need to express the good or bad of a thing, we will use the needs of “good”, “bad”, and “general”. We assume that the existing linguistic term set (LTS)  $S$  is as follows, and the language granularity of LTS is symmetric and uniform.

$$S = \{s_{-3} = \text{none}, s_{-2} = \text{very low}, s_{-1} = \text{low}, s_0 = \text{medium}, s_1 = \text{high}, s_2 = \text{very high}, s_3 = \text{perfect}\}$$

However, when we want to express “a little good” or “excellent”, the LTS cannot accurately express such semantics. Therefore, some scholars have defined a DHLTS, and the specific expression form is as follows.

$$S = \{\dot{S}_{t(\ddot{S}_k)} \mid t = -\tau, \dots, -1, 0, 1, \dots, \tau; k = -\xi, \dots, -1, 0, 1, \dots, \xi\} \quad (1)$$

where  $\dot{s}_t$  and  $\ddot{s}_k$  are the first and second LTS, respectively, and  $t$  and  $k$  is the subscript symmetry number of LTS.

For a DHLTS, you can express  $\phi \times \varphi$  kinds of semantics,  $\phi = 2\tau$ ,  $\varphi = 2\xi$ . Let  $t = k = 3$ ,  $\dot{s}_t = \{\dot{s}_{-3} = \text{none}, \dot{s}_{-2} = \text{very low}, \dot{s}_{-1} = \text{low}, \dot{s}_0 = \text{medium}, \dot{s}_1 = \text{high}, \dot{s}_2 = \text{very high}, \dot{s}_3 = \text{perfect}\}$ .  $\ddot{S}_k = \{\ddot{S}_{-3} = \text{far from}, \ddot{S}_{-2} = \text{only a little}, \ddot{S}_{-1} = \text{a little}, \ddot{S}_0 = \text{just right}, \ddot{S}_1 = \text{much}, \ddot{S}_2 = \text{very much}, \ddot{S}_3 = \text{entirely}\}$  and a little good can be expressed as  $\dot{S}_{1(\ddot{S}_{-2})}$ .

In order to ensure the logic of the evaluation language, the subscript symmetric number is specified as follows.

- (1). If  $t \geq 0$ , then  $\ddot{S}_k = \{\ddot{S}_{-3} = \text{far from}, \ddot{S}_{-2} = \text{only a little}, \ddot{S}_{-1} = \text{a little}, \ddot{S}_0 = \text{just right}, \ddot{S}_1 = \text{much}, \ddot{S}_2 = \text{very much}, \ddot{S}_3 = \text{entirely}\}$ .
- (2). If  $t < 0$ , then  $\ddot{S}_k = \{\ddot{S}_{-3} = \text{entirely}, \ddot{S}_{-2} = \text{very much}, \ddot{S}_{-1} = \text{much}, \ddot{S}_0 = \text{just right}, \ddot{S}_1 = \text{a little}, \ddot{S}_2 = \text{only a little}, \ddot{S}_3 = \text{far from}\}$ .
- (3). If  $t = \tau$ , then  $\ddot{S}_k = \{\ddot{S}_{-3} = \text{far from}, \ddot{S}_{-2} = \text{only a little}, \ddot{S}_{-1} = \text{a little}, \ddot{S}_0 = \text{just right}\}$ .
- (4). If  $t = -\tau$ , then  $\ddot{S}_k = \{\ddot{S}_0 = \text{just right}, \ddot{S}_1 = \text{a little}, \ddot{S}_2 = \text{only a little}, \ddot{S}_3 = \text{far from}\}$ .

### 2.2. Hesitant Fuzzy Linguistic Terms Set

Torra proposed the concept of intuitionistic fuzzy sets in 2010 [35]. If  $U$  is the universe, finite and non-empty,  $A = \{x, h_A(x) \mid x \in X\}$  is said to be a hesitant fuzzy set on  $U$ , where  $h_A(x)$  is a hesitant fuzzy element (HFE), consisting of some values in  $[0, 1]$  interval [36].

For example,  $U = \{y_1, y_2, y_3\}$ ,  $h_A(y_1) = \{0.9, 0.3\}$ ,  $h_A(y_2) = \{0.1, 0.4, 0.6\}$ ,  $h_A(y_3) = \{0.3, 0.2, 0.7, 0.8\}$ , then the hesitation fuzzy set (HFS)  $A$  can be expressed as  $A = \{y_1, \{0.9, 0.3\}, y_2, \{0.1, 0.4, 0.6\}, y_3, \{0.3, 0.2, 0.7, 0.8\}\}$ . On this basis, some scholars put forward the concept of HFLTS by marking  $U$  as a continuous and orderly language set [37]. Let  $x_i \in U$  be fixed and  $S = \{s_t \mid t = -\tau, \dots, -1, 0, 1, \dots, \tau\}$  be LTS. So, HFLTS can be expressed as

$$H_S = \{x_i, h_S(x_i) \mid x_i \in U\} \quad (2)$$

$$h_S(x_i) = \{s_{\phi_l}(x_i) \mid s_{\phi_l}(x_i) \in S; l = 1, \dots, L; \phi_l \in \{-\tau, \dots, -1, 0, 1, \dots, \tau\}\} \quad (3)$$

where  $L$  is the number of linguistic terms in  $h_S(x_i)$  and  $s_{\phi_l}$  in each  $h_S(x_i)$  is the continuous terms in  $S$  [38], and  $h_S(x_i)$  indicates the possibility,  $x_i$  belongs to  $U$  and  $h_S(x_i)$  is called a hesitant fuzzy linguistic element (HFLE).

Moreover, the expression mechanism of the HFLE is closer to people's logical thinking, and can clearly express fuzzy semantics. Generally, it participates in the confirmation of the final result in two ways: one is through direct participation in fuzzy language, and the other is through the transformation of fuzzy language into digital form [39]. In this paper, we convert the language set into numerical values to participate in the determination of the final results because this will make our final evaluation results more intuitive. The 2-tuple linguistic model and the linguistic alphabet are common methods to transform language sets [40,41]. In order to hesitate about the rationality of fuzzy language set transformation, Gou et al. developed the concept of equivalent function, and the specific calculation formula is as follows [42].

Let  $S = \{s_t \mid t = -\tau, \dots, -1, 0, 1, \dots, \tau\}$  be LTS,  $h_S(x_i) = \{s_{\phi_l}(x_i) \mid s_{\phi_l}(x_i) \in S; l = 1, \dots, L; \phi_l \in [-\tau, \tau]\}$  be an HFLE with  $L$  is the number of linguistic terms in  $h_S(x_i)$ . Suppose  $h_\sigma = \{\sigma_l \mid \sigma_l \in [0, 1]; l = 1, \dots, L\}$  is an HFE. If  $\sigma_l$  and  $\phi_l$  of the linguistic term  $s_{\phi_l}$  express the same meaning at symmetric language granularity, the mutual transformation functions between them are  $f$  and  $f^{-1}$ . The specific expression is given as follows.

$$f : [-\tau, \tau] \rightarrow [0, 1], f(\phi_l) = \frac{\phi_l + \tau}{2\tau} = \sigma_l \quad (4)$$

$$f^{-1} : [0, 1] \rightarrow [-\tau, \tau], f^{-1}(\sigma_l) = (2\sigma_l - 1)\tau = \phi_l \quad (5)$$

where  $\phi_l$  is a linguistic term, and  $\sigma_l$  is the membership degree.

Based on Equations (4) and (5), the transformation functions between HFLTS  $h_S$  and HFE  $h_\sigma$  are as follows.

$$F : \phi \rightarrow \Theta, F(h_S) = F(\{s_{\phi_l} \mid s_{\phi_l} \in S; l = 1, \dots, L; \phi_l \in [-\tau, \tau]\}) = \{\sigma_l \mid \sigma_l = f(\phi_l)\} = h_\sigma \quad (6)$$

$$F^{-1} : \Theta \rightarrow \phi, F^{-1}(h_\sigma) = F^{-1}(\{\sigma_l \mid \sigma_l \in [0, 1]; l = 1, \dots, L\}) = \{\phi_l \mid \phi_l = f^{-1}(\sigma_l)\} = h_S \quad (7)$$

where  $\phi$  is LTS and  $\Theta$  is the set of all HFLEs.

The basic following functions and the operation formula of the HFLTS are as follows.

Let  $h_{S_1} = \{s_{\phi_l}^1 \mid s_{\phi_l}^1 \in S; l = 1, 2, \dots, L; \phi_l \in [-\tau, \tau]\}$  and  $h_{S_2} = \{s_{\phi_l}^2 \mid s_{\phi_l}^2 \in S; l = 1, 2, \dots, L; \phi_l \in [-\tau, \tau]\}$  are two HFLTSs.

$$(1). \quad h_{S_1} \oplus h_{S_2} = F^{-1}\left(\bigcup_{\gamma_1 \in F(h_{S_1}), \gamma_2 \in F(h_{S_2})} \gamma_1 + \gamma_2 - \gamma_1\gamma_2\right);$$

$$(2). \quad h_{S_1} \otimes h_{S_2} = F^{-1}\left(\bigcup_{\gamma_1 \in F(h_{S_1}), \gamma_2 \in F(h_{S_2})} \gamma_1\gamma_2\right);$$

$$(3). \quad \lambda h_{S_1} = F^{-1}\left(\bigcup_{\gamma_1 \in F(h_{S_1})} \{1 - (1 - \gamma_1)^\lambda\}\right);$$

$$(4). \quad (h_{S_1})^\lambda = F^{-1}\left(\bigcup_{\gamma_1 \in F(h_{S_1})} \{\gamma_1^\lambda\}\right).$$

In the formula,  $\gamma$  represents a real number.

### 2.3. Double Hierarchy Hesitant Fuzzy Linguistic Term Set

On this basis, we propose the DHHFLTS,  $H_s = \left\{ \dot{S}_{\phi_l \langle \ddot{s}_{\phi_l} \rangle} \mid \dot{S}_{\phi_l \langle \ddot{s}_{\phi_l} \rangle} \in S; l = 1, \dots, L; t = [-\tau, \tau]; k = [-\xi, \xi] \right\}$ ,  $S = \left\{ \dot{S}_{t \langle \ddot{s}_k \rangle} \mid t = -\tau, \dots, -1, 0, 1, \dots, \tau; k = -\xi, \dots, -1, 0, 1, \dots, \xi \right\}$ . It also divides language granularity based on symmetric concepts, with L being the subscript symmetry number of LTS in  $H_s$ , as shown in Figure 1.

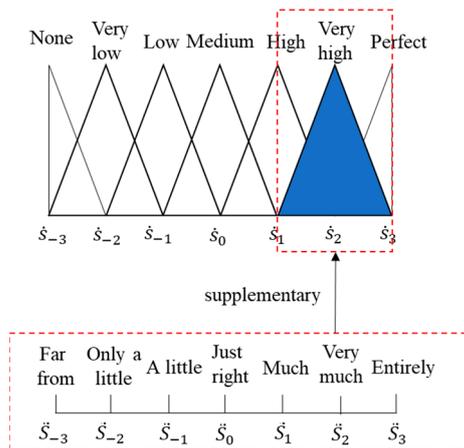

Figure 1. The second hierarchy LTS subscript symmetry number of  $s_2$  (very high).

In Figure 1, let  $t = k = 3$ , then the first hierarchy LTS is  $\dot{S}_\tau$ , the second hierarchy LTS is  $\ddot{S}_k$ , and the second hierarchy LTS is a supplement to the first hierarchy LTS.

Next, based on the transformation functions and operation formula of the HFLTS, we formulate the transformation functions and operation formula of the DHHFLTS. Let  $H_s = \left\{ \dot{S}_{\phi_l \langle \ddot{s}_{\phi_l} \rangle} \mid \dot{S}_{\phi_l \langle \ddot{s}_{\phi_l} \rangle} \in S; l = 1, \dots, L; t = [-\tau, \tau]; k = [-\xi, \xi] \right\}$  is DHHFLTS,  $S = \left\{ \dot{S}_{t \langle \ddot{s}_k \rangle} \mid t = -\tau, \dots, -1, 0, 1, \dots, \tau; k = -\xi, \dots, -1, 0, 1, \dots, \xi \right\}$ . Suppose  $h_\mu = \{ \mu_l \mid \mu_l \in [0, 1]; l = 1, \dots, L \}$  is an HFE. If  $\mu_l$  and  $\phi_l \langle \phi_l \rangle$  of the linguistic term  $\dot{S}_{\phi_l \langle \ddot{s}_{\phi_l} \rangle}$  express the same meaning, the mutual transformation functions between them are  $q$  and  $q^{-1}$ . The specific expression is as follows.

$$q : [-\tau, \tau] \times [-\xi, \xi] \rightarrow [0, 1], f(\phi_l, \phi_l) \begin{cases} \frac{1}{\tau} \times \frac{\phi_l + \xi}{2\xi} + \frac{\tau + \phi_l - 1}{2\tau} = \frac{\phi_l + (\tau + \phi_l)\xi}{2\xi\tau} = \mu_l, \text{ if } -\tau + 1 \leq \phi_l \leq \tau - 1 \\ \frac{1}{2\tau} \times \frac{\phi_l + \xi}{\xi} + \frac{\tau + \phi_l - 1}{2\tau} = \frac{\phi_l + (\tau + \phi_l)\xi}{2\xi\tau} = \mu_l, \text{ if } \phi_l = \tau \\ \frac{1}{2\tau} \times \frac{\phi_l}{\xi} = \frac{\phi_l}{2\xi\tau} = \mu_l, \text{ if } \phi_l = -\tau \end{cases} \quad (8)$$

$$q^{-1} : [0, 1] \rightarrow [-\tau, \tau] \times [-\xi, \xi] \begin{cases} [2\tau\mu_l - \tau] + 1 < \ddot{S}_{\xi((2\tau\mu_l - \tau - [2\tau\mu_l - \tau]) - 1)} >, \text{ if } 1 - \tau \leq 2\tau\mu_l - \tau \leq \tau - 1 \\ \tau < \ddot{S}_{\xi(2\tau\mu_l - \tau - [2\tau\mu_l - \tau]) - \xi} >, \text{ if } \tau - 1 \leq 2\tau\mu_l - \tau \leq \tau \\ 1 - \tau < \ddot{S}_{\xi((2\tau\mu_l - \tau - [2\tau\mu_l - \tau]) - 1)} >, \text{ if } -\tau \leq 2\tau\mu_l - \tau \leq 1 - \tau \end{cases} \quad (9)$$

where  $\phi_l$  and  $\phi_l$  are the subscript numbers of the first hierarchy LTS and the second hierarchy LTS, respectively, and represents the rounding symbol.

Based on Equations (8) and (9), the transformation functions between DHHFLTS  $H_S$  and HFE  $h_\mu$  is as follows.

$$Q : \phi \times \varphi \rightarrow \Theta, Q(H_S) = \{\mu \mid \mu_l = q(\phi_l, \varphi_l)\} = h_\mu \quad (10)$$

$$Q^{-1} : \Theta \rightarrow \phi \times \varphi = \left\{ s_{\phi_l \langle o_{\varphi_l} \rangle} \mid \phi_l \langle o_{\varphi_l} \rangle = q^{-1}(\mu_l) \right\} = H_S \quad (11)$$

where  $\phi$  and  $\varphi$  is LTS and  $\Theta$  is the set of all HFLEs.

The operation formula of the DHHFLTS is as follows. Let  $H_{S_1} = \left\{ \dot{s}_{\phi_l \langle \dot{s}_{\varphi_l}^1 \rangle}^1 \mid \dot{s}_{\phi_l \langle \dot{s}_{\varphi_l}^1 \rangle}^1 \in S; l = 1, \dots, L; t = [-\tau, \tau]; k = [-\xi, \xi] \right\}$  and  $H_{S_2} = \left\{ \dot{s}_{\phi_l \langle \dot{s}_{\varphi_l}^2 \rangle}^2 \mid \dot{s}_{\phi_l \langle \dot{s}_{\varphi_l}^2 \rangle}^2 \in S; l = 1, 2, \dots, L_2; \phi_l \in [-\tau, \tau] \right\}$  are two DHHFLTSs, with  $S = \left\{ \dot{s}_{t \langle \dot{s}_k \rangle} \mid t = -\tau, \dots, -1, 0, 1, \dots, \tau; k = -\xi, \dots, -1, 0, 1, \dots, \xi \right\}$ .

$$H_{S_1} \oplus H_{S_2} = Q^{-1} \left( \bigcup_{\eta_1 \in Q(H_{S_1}), \eta_2 \in Q(H_{S_2})} \eta_1 + \eta_2 - \eta_1 \eta_2 \right) \quad (12)$$

$$H_{S_1} \otimes H_{S_2} = Q^{-1} \left( \bigcup_{\eta_1 \in Q(H_{S_1}), \eta_2 \in Q(H_{S_2})} \eta_1 \eta_2 \right) \quad (13)$$

$$\lambda H_{S_1} = Q^{-1} \left( \bigcup_{\eta_1 \in Q(H_{S_1})} \left\{ 1 - (1 - \eta_1)^\lambda \right\} \right) \quad (14)$$

$$(H_{S_1})^\lambda = Q^{-1} \left( \bigcup_{\eta_1 \in Q(H_{S_1})} \left\{ \eta_1^\lambda \right\} \right) \quad (15)$$

where  $Q^{-1}$  of calculation rule refers to the calculation of Equation (11),  $\lambda$  represents the weight in the actual calculation process of this paper,  $\eta_1$  and  $\eta_2$  are the HFLEs of the DHHFLTSs  $H_{S_1}$  and  $H_{S_2}$ , respectively.

### 3. Weight of Evaluation Members and Influencing Factors

#### 3.1. Entropy Weight Method for Evaluating Personnel Weight

According to the definition of information entropy, the entropy value of an index can be determined by using the dispersion of the index. The smaller the information entropy value included, the greater the influence of the index on the comprehensive evaluation. If the values of an index are all equal, the index will not play a role in the comprehensive evaluation [43].

The idea of the entropy weight method is presented in this paper. There is a big difference between the evaluation results of evaluation members and those of other evaluation members when evaluating an influencing factor. According to the definition of information entropy, it can be determined that the evaluation dispersion of this evaluation member is large. Therefore, the greater the impact of evaluation members on the comprehensive evaluation, the greater the weight. Based on this idea, we obtain the formula for calculating the weight of evaluation members as follows.

$$\lambda_p = \frac{\sum_{q=1; q \neq p}^b \sum_{j=1}^m \sum_{i=1}^n d(H_{S_{ij}}^p, H_{S_{ij}}^q)}{\sum_{p=1}^b \sum_{q=1; q \neq p}^b \sum_{i=1}^m \sum_{j=1}^n d(H_{S_{ij}}^p, H_{S_{ij}}^q)} \quad (16)$$

$$d(H_{\dot{s}_s}^{1j}, H_{\dot{s}_s}^{2j}) = \frac{1}{L} \sum_{l=1}^L \left( \left| Q \left( \dot{s}_{\phi_l \langle \dot{s}_{\varphi_l} \rangle}^{1j} \right) - Q \left( \dot{s}_{\phi_l \langle \dot{s}_{\varphi_l} \rangle}^{2j} \right) \right| \right) \quad (17)$$

In Equation (16),  $i$  is the number of influencing factors,  $i = 1 \dots n$ ,  $j$  is the number of failure modes,  $j = 1 \dots m$ , and  $q$  is the number of evaluation members,  $q = 1, \dots, p \dots b$ .

In Equation (17),  $L$  is the number of LTS.

### 3.2. Using K-Means Clustering Algorithm to Calculate the Weight of Influencing Factors

K-means clustering is a clustering algorithm based on sample set partition. K-means clustering divides the sample set into K subsets to form K classes. n samples are divided into K classes. The center distance from each sample to its class is the smallest. Each sample belongs to only one class [44].

Let  $X = \{x_1, x_2, \dots, x_i, \dots, x_n\}$  is a given dataset containing D-dimensional data, where  $x_i \in R^d$ . The K-means clustering algorithm to the data object for the class K clusters, namely  $C^1 = \{c_r^1, r = 1, 2, \dots, K\}$ . For dividing cluster  $c_r^1$ , the initial cluster center is  $\mu_r^1$ . The Euclidean distance between data object and cluster center in space is calculated as follows:

$$J(c_r^1) = \sum_{x_i \in X} d(x_i - \mu_r^1)^2 \quad (18)$$

where  $r = 1, 2, \dots, K$  is number of clusters. Similarly, calculate the distance from the data point to the center point of each cluster. According to the principle of minimum distance, the center point of the cluster is obtained from the new cluster division. Assuming that the new cluster is  $C^2 = \{c_r^2, r = 1, 2, \dots, K\}$ , the calculation formula of the new cluster center  $\mu_r^2$  is as follows.

$$\mu_r^2 = \frac{1}{N} \sum_{x_i \in c_r^2} x_i \quad (19)$$

where N is the number of new cluster r data.

This process will be repeated until the termination conditions are met to obtain the final cluster  $C^n = \{c_r^n, r = 1, 2, \dots, K\}$ . Assuming that the final cluster center point of cluster R is  $c_r^n = \{S_r, O_r, D_r\}$ , the formula for calculating the weight of influencing factors is as follows.

Firstly, the evaluation information of influencing factor S of all evaluation members of j failure mode in the cluster is normalized.

$$\Gamma H_S^j(S) = \frac{\sum_{q=1}^b \lambda_q \wedge Q(H_S^j(S))}{\sum_{j=1}^m \sum_{q=1}^b \lambda_q \wedge Q(H_S^j(S))} \quad (20)$$

where  $\lambda_q$  is the weight of the evaluation member q,  $H_S^j(S)$  is the evaluation of the evaluation member on the influence factor S of the failure mode j by the DHHFLTS, and j is the number of failure modes,  $j = 1 \dots m$ .

Then calculate the distance between the normalized evaluation information and the cluster center point  $S_r$ .

$$l_s = \sum_{j=1}^m \sum_{r \in C_r} |d(Q^{-1}(\Gamma H_S^j(S)) - S_r)| \quad (21)$$

Finally, calculate the ratio between the  $l_s$  and L. L is the distance between the evaluation information of each influencing factor of the evaluator and the center point  $c_r^n$ .

$$L = l_s + l_O + l_D \quad (22)$$

$$\omega_s = \frac{l_s}{L} \quad (23)$$

In Equation (23),  $l_s$  is the distance from the S evaluation data to the final cluster point of S in each cluster. Similarly, where  $l_O$  is the distance between the evaluator's evaluation of occurrence and the center point  $O_r$ .

Based on the idea of traditional FMEA to calculate the RPN value and sort it, we calculate the failure mode score value. The calculation formula is as follows.

$$score = \omega_S \wedge \Gamma H_S^j(S) + \omega_O \wedge \Gamma H_S^j(O) + \omega_D \wedge \Gamma H_S^j(D) \quad (24)$$

where  $j$  is the failure mode.

#### 4. The Proposed FMEA Model

In the previous section, we described the definitions and calculation formulas of the DHHFLTS and the K-means clustering algorithm. This section mainly introduces the calculation steps of the new method proposed in this paper.

Step 1: Preparation in advance

Firstly, we collect failure modes and establish an evaluation team and determine the evaluation language set. Then, the evaluator uses the DHHFLTS to evaluate the failure mode.

Step 2: Solving the weight of evaluation members

The DHHFLTS given by evaluation members is standardized, and its information entropy is calculated. The entropy weight method is used to calculate the weight of evaluation personnel.

Step 3: Using the K-means clustering algorithm by finding the center of evaluation information.

Step 3.1: The aggregated evaluation information is taken as the sample of the K-means clustering algorithm, and the K initial center values are randomly selected.

Step 3.2: We initialize the algorithm by using random K initial center values, and calculate the distance between each failure mode evaluation information and the initial center point.

Step 3.3: The failure mode with the shortest distance from the initial center point is selected to be classified into one category. The average value of evaluation information in each category is calculated, and the center point is updated.

Step 3.4: We judge whether the center point changes. If it changes, return to Step 3.2. If it does not change, output the final center point.

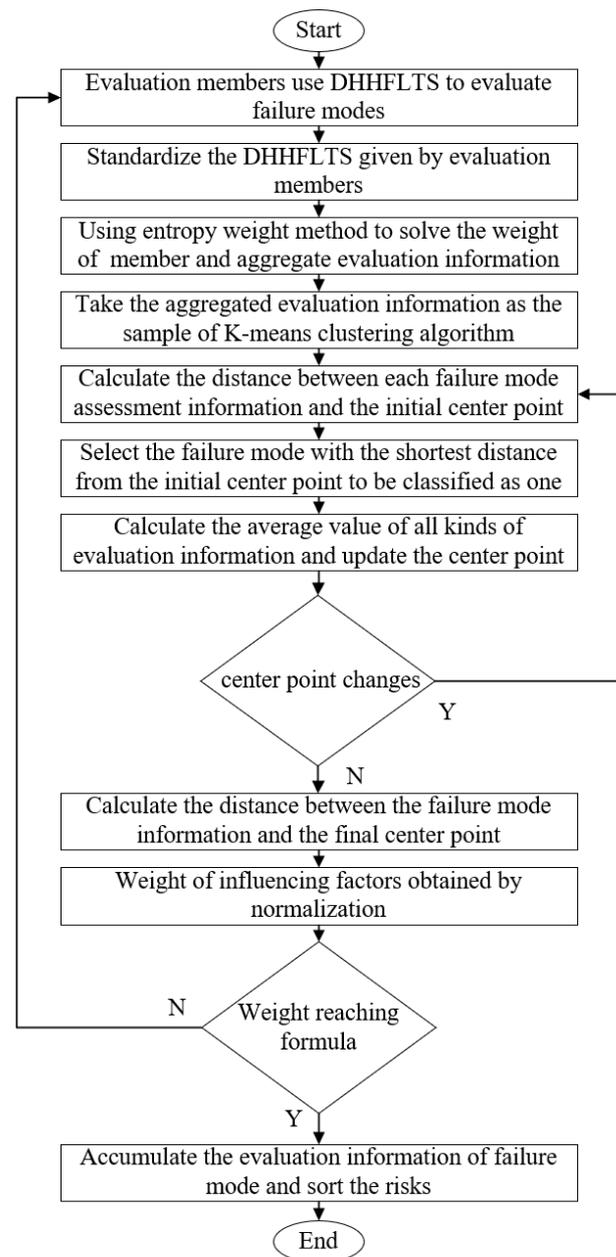

Step 4: Calculating the weight of influencing factors

We calculate the distance between the failure mode assessment information and the final center point, and normalize to obtain the weight of the influencing factors. If the weight calculation of influencing factors does not reach the consensus of evaluation members, return to Step 2.

Step 5: Obtaining the evaluation results

The evaluation information of the failure mode is aggregated, the evaluation information of the failure mode is accumulated, and the risk is sorted.

The detailed calculation process is shown in Figure 2.

**Figure 2.** FMEA model based on DHHFLTS and K-means clustering algorithm.

## 5. A Case Study

This section is divided into two: Section 5.1 shows that an electronic technology company used the new method to analyze the design process of an electromagnet product. The results calculated by this method and compared with other methods are analyzed in Section 5.2.

### 5.1. A Case Analysis

An electronic technology company plans to produce a batch of electromagnet products for blood collection equipment. The design diagram of the product is shown in Figure 3. The design scheme of the product is analyzed from three aspects: structure, function, and failure. Nine failure modes are sorted out based on the consensus points of the three aspects, FM1–FM9, as shown in Table 1. The company selects three engineers from R&D, production, sales, and three parts to form an evaluation team, which is recorded as TM1–TM3, and analyzes nine failure modes.

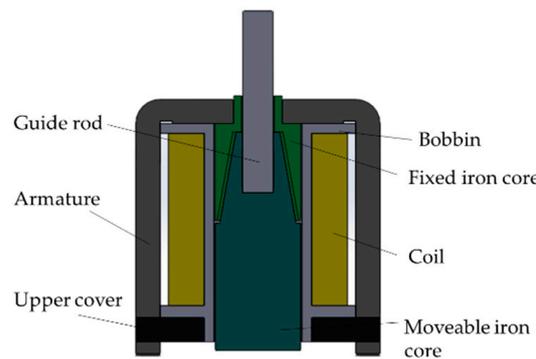

Figure 3. Structure diagram of pilot-type electromagnet.

The first step is to determine the evaluation DLS, making  $t = k = 3$ , so the set of double hesitation fuzzy languages is  $\dot{s}_t = \{\dot{s}_{-3} = \text{none}, \dot{s}_{-2} = \text{very low}, \dot{s}_{-1} = \text{low}, \dot{s}_0 = \text{medium}, \dot{s}_1 = \text{high}, \dot{s}_2 = \text{very high}, \dot{s}_3 = \text{perfect}\}$ ,  $\ddot{S}_k = \{\ddot{S}_{-3} = \text{far from}, \ddot{S}_{-2} = \text{only a little}, \ddot{S}_{-1} = \text{a little}, \ddot{S}_0 = \text{just right}, \ddot{S}_1 = \text{much}, \ddot{S}_2 = \text{very much}, \ddot{S}_3 = \text{entirely}\}$ . The assessment members use DHHFLTS to assess the failure mode according to the assessment criteria. The results are shown in Table 2. The first hierarchy LTS determines the evaluation range, while the second hierarchy LTS is a supplement to the first hierarchy LTS, that is, a fine delimitation of the large range of the first-level language. Therefore, the first hierarchy LTS is more important than the second hierarchy LTS in the evaluation process, so the evaluation criteria given in this paper are based on the first hierarchy LTS. The evaluation criteria of severity  $S$ , occurrence  $O$ , and detection  $D$  are shown in Tables 3–5.

Table 2 is transformed into a membership degree through Equations (8) and (10). For example,  $\dot{S}_{3(\ddot{s}_{-1})} = \frac{-1+(3+3)3}{2 \times 3 \times 3} = \frac{17}{18} = 0.944$ . Similarly, all DHHFLTSs in Table 2 are calculated, as shown in Table 6.

According to the calculation Equations (12)–(17), the weights of three evaluation members are  $\lambda_1 = 0.31$ ,  $\lambda_2 = 0.342$ , and  $\lambda_3 = 0.348$ . Table 3 is aggregated based on the weight of evaluation members. For example, the aggregation of influencing factors  $S$  of failure mode F1 is  $0.994^{0.310} + 0.833^{0.342} + 0.778^{0.348} = 2.838$ . The aggregated data are normalized to obtain the input samples of K-means clustering, as shown in Table 7.

Table 1. Failure Mode Summary.

No.	Failure Mode	Failure Consequence	Failure Reason
FM1	Poor insulation	Product leakage	Insufficient material insulation grade
FM2	The reel is not strong enough	Product leakage	(a) Low strength of plastic raw materials (b) Improper design of spool structure (c) Excessive tension design
FM3	Short circuit of product after power on	Unable to drive the action of the customer organization	Insufficient temperature resistance grade of materials
FM4	Insufficient strength of end pin	Affect customer installation	Improper soldering and assembly design
FM5	Poor surface roughness	Impact on product life	Improper design of dimensional tolerance
FM6	Poor concentricity	Customer cannot install	Improper design of dimensional tolerance
FM7	Insufficient magnetic force	Customer cannot use it	(a) The magnetic permeability of the material is insufficient (b) Improper designs
FM8	Residual magnetism	Customer cannot use it	(a) The magnetic permeability of the material is insufficient (b) Improper designs
FM9	Insufficient retention	Blood backflow during use	Insufficient winding and improper process

**Table 3.** Severity assessment criteria.

Influence	Severity	Grade (First Hierarchy LTS)
Failure of laws and regulations affecting safety or government	Affects work safety or does not comply with government regulations without any warning	Perfect
	Impact on work safety or non-compliance with government regulations in case of warning	Very high
Loss or reduction of expected functions	Loss of basic functions (electromagnet cannot work, which will not affect safety)	High
Loss or decrease of secondary functions	Loss of secondary function (loss of comfort and convenience function)	Medium
Customer feedback	Electromagnet can work, most customers (>75%) perceive noise and appearance	Low
	Electromagnet can work, and most customers (50%) perceive noise and appearance	Very low
No impact	No detectable impact	None

**Table 4.** Occurrence assessment criteria.

Familiarity with Design	Occurrence of Cause	Grade (First Hierarchy LTS)
Very low	New technology and new design without corresponding history	Perfect
Low	Inevitable failure due to new design, new application or change of operating conditions	Very high
	New design, new application or change of operating conditions may lead to failure	High
Medium	Frequent failures in similar designs and design tests	Medium
	Occasional failures in similar designs and design tests	Low
High	Isolated failures in almost identical designs and design tests	Very low
Very high	By preventing controllable failures	None

Table 5. Detection assessment criteria.

Difficulty of Survey	Possibility of Discovery through Design Control	Grade (First Hierarchy LTS)
Very high	No current design control, cannot be found or analyzed	VVL
High	Weak discovery ability in design analysis	VL
Medium	Verification using tested products prior to product release	L
	Verification of products using failure test before product release	M
Low	Use failure test to confirm products before design freezing	H
	Use the old test to confirm the product before design freezing	VH
Very low	Failure modes cannot occur because of a fully preventable design	EH

Table 7. Clustering initial sample data.

Failure Mode	Evaluation Information		
	S	O	D
FM1	0.117	0.124	0.096
FM2	0.111	0.037	0.123
FM3	0.111	0.116	0.114
FM4	0.106	0.131	0.114
FM5	0.118	0.137	0.109
FM6	0.116	0.047	0.065
FM7	0.092	0.127	0.113
FM8	0.111	0.037	0.123
FM9	0.118	0.124	0.117

We classify data into two categories: one is high-risk failure mode, and the other is low-risk failure mode. According to Equations (18) and (19), after 5 times, two types of final cluster centers are obtained, namely high-risk cluster center  $C_h = \{C_S = 0.094, C_O = 0.042, C_D = 0.114\}$  and low-risk cluster center  $C_l = \{C_S = 0.116, C_O = 0.131, C_D = 0.110\}$ , as shown in Figure 4.

According to Equations (20)–(23), the weight of the influencing factors is  $\omega = \{\omega_S = 0.501, \omega_O = 0.289, \omega_D = 0.211\}$ . Then, the score of FM1 is  $score = 0.117^{0.501} + 0.124^{0.289} + 0.096^{0.211} = 1.499$ . Similarly, we calculate the scores of other failure modes, as shown in Table 8.

According to the analysis results, the top three failure modes of risk ranking are optimized. In order to eliminate the harm caused by insufficient retention force, we use a tensile machine to spot check the retention force of finished products in the laboratory to ensure that the retention force of each outgoing product meets the requirements. Firstly, we use the upper and lower collect to fix the test parts, use the console to control the hydraulic

stay rod to squeeze the test sample, and read the retention force of the parts on the monitor. The product test diagram is shown in Figure 5.

Failure Mode	Score	Sort
FM1	1.49932	6
FM2	1.36163	8
FM3	1.50193	5
FM4	1.51328	4
FM5	1.53291	2
FM6	1.31643	9
FM7	1.48521	7
FM8	1.5267	3
FM9	1.59069	1

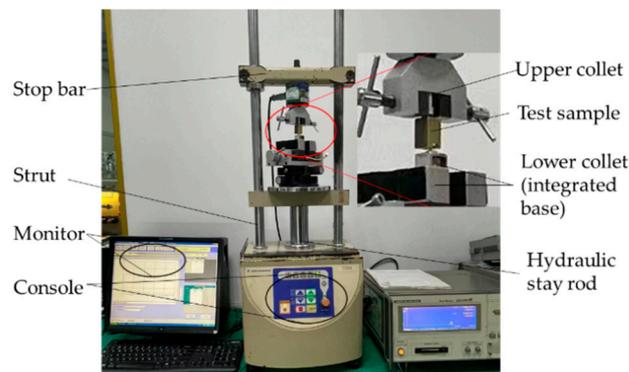

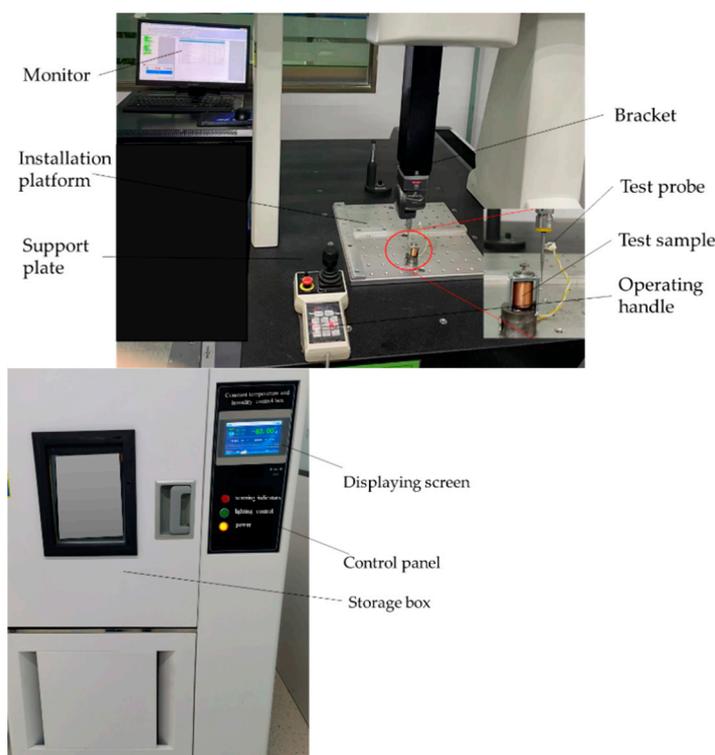

Figure 5. Tensile machine test diagram.

In order to eliminate residual magnetism, we use the heating method, which is to heat the parts to a certain temperature and keep them warm for a certain time to realize demagnetization. In order to improve the processing accuracy of products, we use a CMM to measure the surface roughness of the product. Firstly, we use the thermostat to heat and insulate the product. The specific steps are to put the product into the storage box, switch on the power, adjust the temperature to  $600^{\circ}$ , and heat it for one hour. After heating, keep the temperature for one hour and take out the product. Then, we send the product to the CMM to start the roughness test. Next, we fix the product on the support plate, operate the test probe, evenly select five points on the measuring surface for testing, and monitor the product surface roughness in real time to facilitate product screening. The test platform is shown in Figure 6.

**Figure 6.** Comprehensive test platform: CMM (top); thermostat (bottom).

Through the analysis results of the newly proposed method, we formulate optimization measures for high-risk failure modes in advance to minimize the possibility of failure in the enterprise product design and production stage.

### 5.2. Comparative Analysis and Discussion

In order to show the advantages of the proposed method, FMEA is proposed for comparative analysis. For these nine failure modes, we use the calculation results of three methods for comparison. The first is the new method proposed in this paper, the second is the method used in Reference [19], and the last is traditional FMEA. They are, respectively, recorded as Sort 1, Sort 2, and Sort 3, as shown in Figure 7.

Based on Figure 7, we analyze Sorting 1 and Sorting 2. These two methods have the same sorting for the four failure modes 9, 5, 8, and 2. Failure Modes 9, 5, and 8 are high-risk failure modes. This proves that these two methods can analyze the failure modes that need to be prevented most. As for the ranking of the later failure modes, the reason is that the weights of the influencing factors calculated by the two methods are different [19] by comparing the matrix of influencing factors in pairs. In this case, we compared the new proposed method.

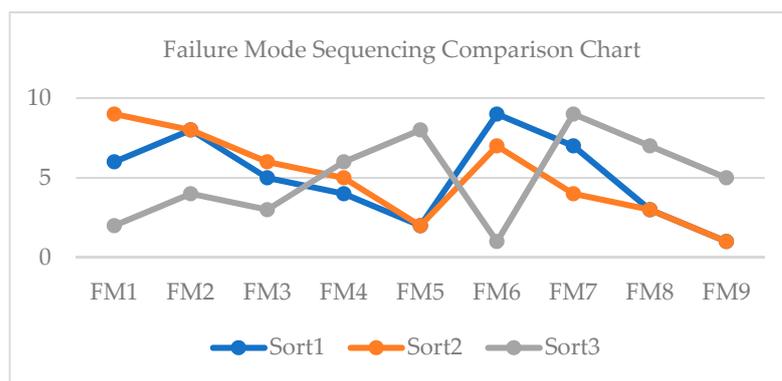

Figure 7. Sorting comparison chart.

The results of traditional FMEA calculation are quite different whether compared with the results of the new method or the results of the literature. This is mainly because when traditional FMEA calculates the RPN, the default influencing factors and the weight of evaluation members are equally divided. In the actual evaluation process, the weight of severity  $S$  is far greater than that of occurrence  $O$  and detection  $D$ . For example, the calculation result of the influence factor weight of the newly proposed method is  $\omega_{sort1} = \{\omega_S = 0.501, \omega_O = 0.289, \omega_D = 0.211\}$ , and the calculation result of the influence factor weight is  $\omega_{sort2} = \{\omega_S = 0.684, \omega_O = 0.182, \omega_D = 0.134\}$ . Therefore, there is a big difference between the calculation results of traditional FMEA and those of the other two methods.

## 6. Conclusions

In order to reflect the evaluation psychology of evaluation members, the symmetrical concepts of the DHHFLTS are used to construct evaluation language sets. Based on the idea of the entropy weight method and the K-means clustering algorithm, this paper also solves the influencing factors and weights of evaluation members. We know that the entropy weight method and the K-means clustering algorithm are the most commonly used methods to solve weights. The high-frequency utilization rate proves the practicability of these two methods. In addition, the calculation process of these two methods is relatively simple, which is more suitable for promotion in electronic enterprises.

In addition, this paper borrows the idea of traditional FMEA to sort the failure modes by calculating the RPN, and then comprehensively calculates the risk ranking of failure modes based on the influencing factors and evaluation member weights. This does not only lose objectivity, but can also avoid the disadvantage of inaccurate risk ranking of failure models due to repeated calculation results to the greatest extent. This paper evaluates a single value based on the evaluation of double-level hesitant fuzzy sets, and whether it can be evaluated by two values in the future. If such an evaluation form is adopted, its corresponding calculation rules, and the calculation formulas of other related methods need to be innovated. Breakthroughs can be found in all these aspects in the future.

In the future, we will further optimize the application using the model revision technology to the new method. The next step in our research is to focus on the computing platform software system of data process and complex computation by using familiar tools. Moreover, the approved method is extended to other electronic products to increase research and application in this area, and further research of the DHHFLTS and the K-means clustering algorithm will have great theoretical value and practical significance.
