* Adjusted for age, sex and BMI. * Additive models were used for genotyping SNPs. ^a Elevated triglycerides (triglycerides ≥ 150 mg/dL). ^b Reduced high-density lipoprotein (HDL) cholesterol (males < 40 mg/dL; females < 50 mg/dL). ^c Elevated fasting glucose (fasting glucose ≥ 100 mg/dL or use of medications for hyperglycemia).

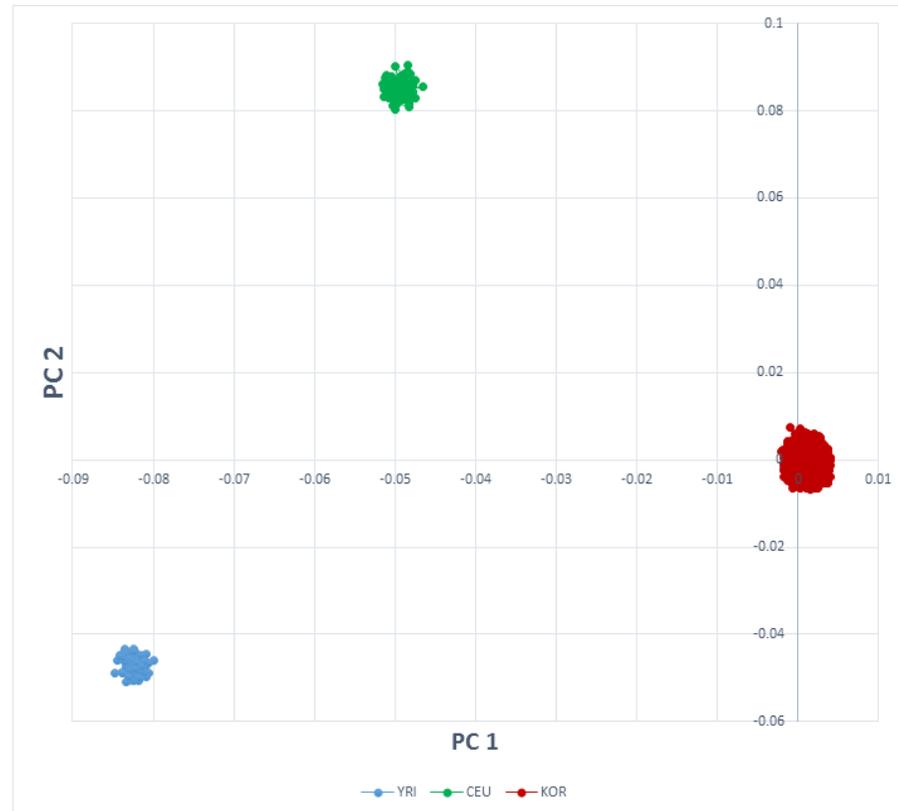

Figure S1. Principle component analysis (PCA) to adjust the population stratification. The total population of the GENIE database⁹ was merged with the YRI and CEU data, which consisted of 1000 genomes, for the PCA. The criteria for marker selections were as follows: quality control of minor allele frequencies >0.05 , call rates >0.05 , Hardy-Weinberg equilibrium ($P > 0.0001$), and autosome. In all, 220,222 overlapping markers were found among the datasets. We randomly selected 20% of the overlapping markers (43,979) for the PCA plot.

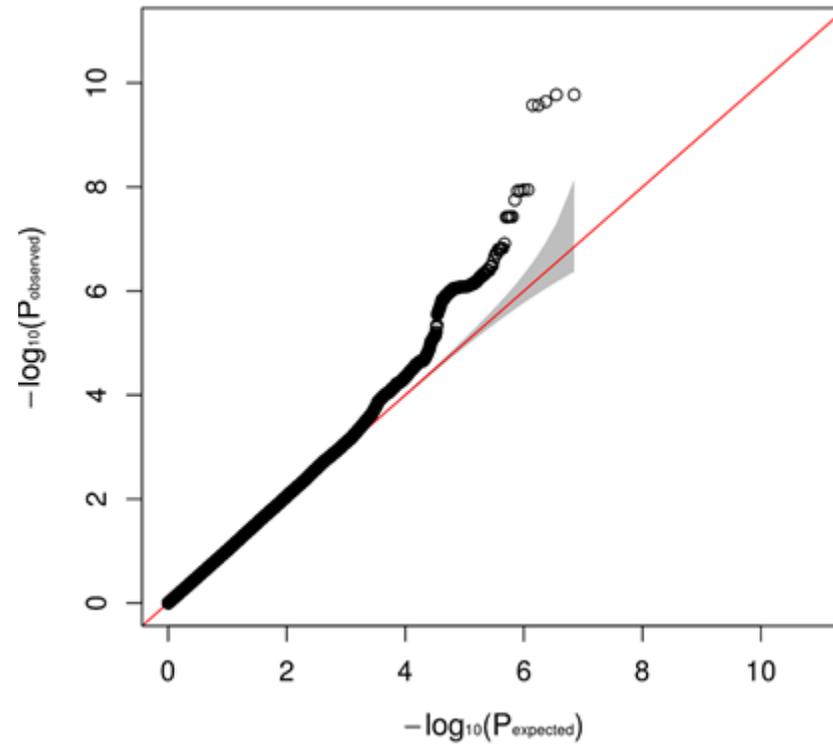

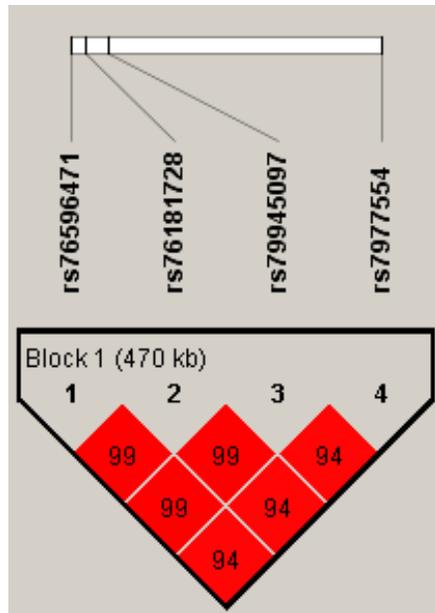

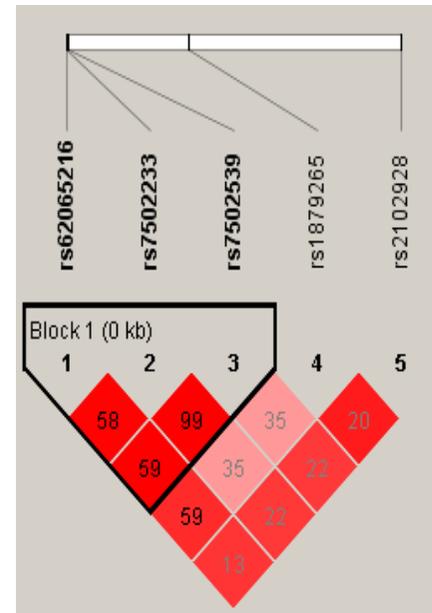

Figure S2. Q-Q plot of the log-transformed NLR genome-wide association study. The variance inflation factor (VIF) is 1.02, which suggests that the type-1 error is well controlled.
