

Supplementary Methods

RNA sequencing and bioinformatics analysis. Total cellular RNA was extracted from the following samples and sequenced on an Illumina HiSeq sequencer at the European Molecular Biology Laboratory (EMBL): PD and CTR iPSCs differentiated into NPCs (two lines each; PD1/PD2 and CTR1/CTR2). RNA libraries were prepared with the TruSeq RNA Sample Preparation Kit V2 (Illumina). Raw RNA-seq reads were quality checked using FastQC (www.bioinformatics.babraham.ac.uk/projects/fastqc/). Contaminants were detected and removed utilizing a combination of an in-house-developed algorithm and already available tools (5). Following pre-processing, GSNAp spliced aligner (6) was utilized to map the RNA-seq reads against the reference genome (GRCh37/hg19 genome assembly). GSNAp has been appropriately parameterized in order to detect novel and known splice junctions. Differential expression analysis was performed using DESeq (7). Specifically, differential expressed genes with fold change >1 ($p<0.05$) were identified using all expressed genes (>10 raw read counts per gene). Correction for false discovery rate (FDR) was not applied due to the limited number of the resulting differential expressed genes. Heat maps were implemented using R/Bioconductor (8, 9) (Clustering: Pearson'scorrelation coefficient, row-wise scaling: centering and scaling using Z-scores). Enrichment analyses were performed against Gene Ontology10 using the hypergeometric distribution, KEGG and Reactome pathway databases. All gene annotations were derived from Ensembl (10). Heat maps were generated using R programming language in RStudio v1.1.456. All gene annotations were derived from Ensembl (10). Gene Ontology (GO) Enrichment analyses were performed using the Database for Annotation, Visualisation and Integrated Discovery (DAVID) v6.8 (<https://david.ncifcrf.gov>).

qPCR analysis. Quantitative PCR analyses were carried out in a Light Cycler96 (Roche) Real time PCR detection system using KAPA SYBR FAST qPCR Master Mix (KapaBiosystems). The analysis of expression levels was based on the comparative CT Method ($2^{-\Delta\Delta CT}$ Method) (Livak and Schmittgen, 2001; Schmittgen and Livak, 2008). Briefly, this approach calculates mean C_T values of the target and reference gene (GAPDH) and the values of the reference gene are subtracted from target gene (ΔCt). The biggest ΔCt value is then subtracted from all samples, giving the $\Delta\Delta Ct$. The negative value of this subtraction ($-\Delta\Delta Ct$) is then used as the exponent of 2 and this value represents the fold change of expression. Differences between PD and CTR mRNA levels of selected transcripts from 3 independent differentiation procedures were assessed by two tailed unpaired T-test ($p<0.05$).

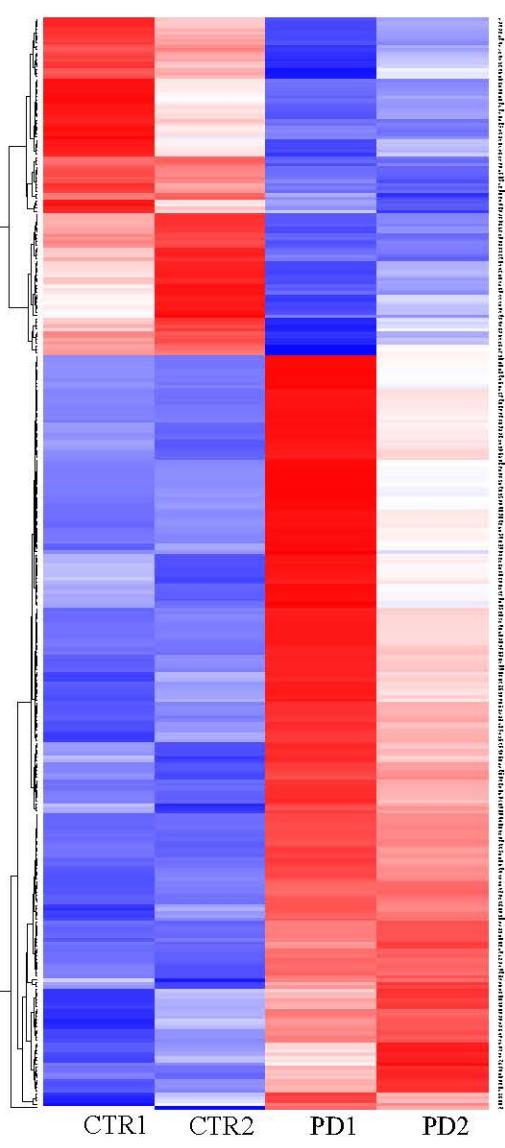

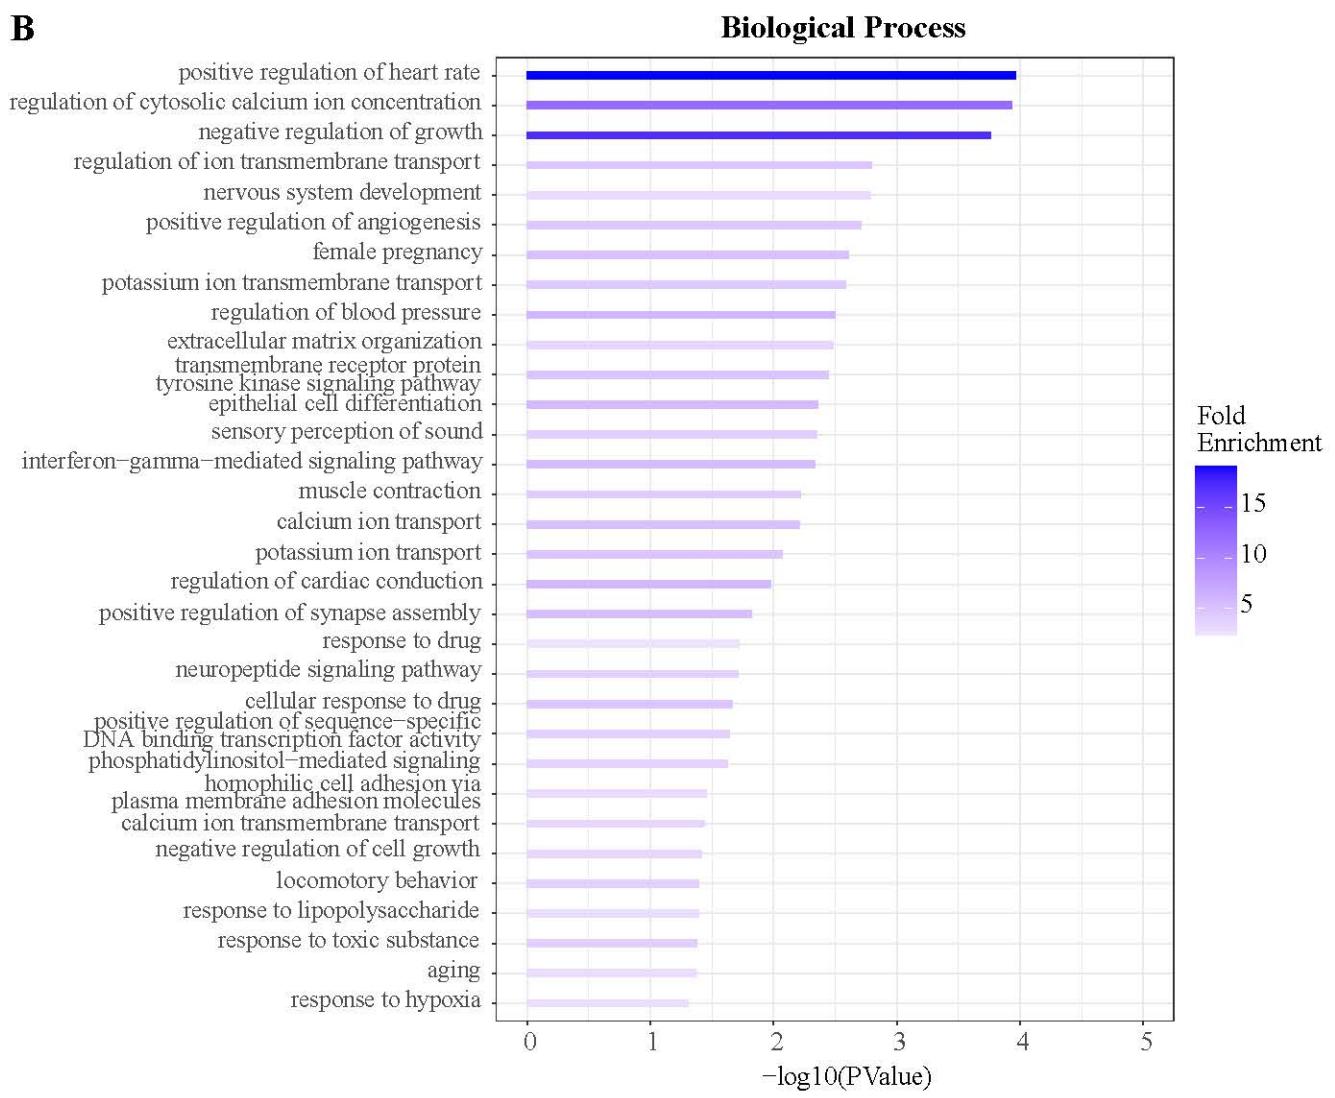

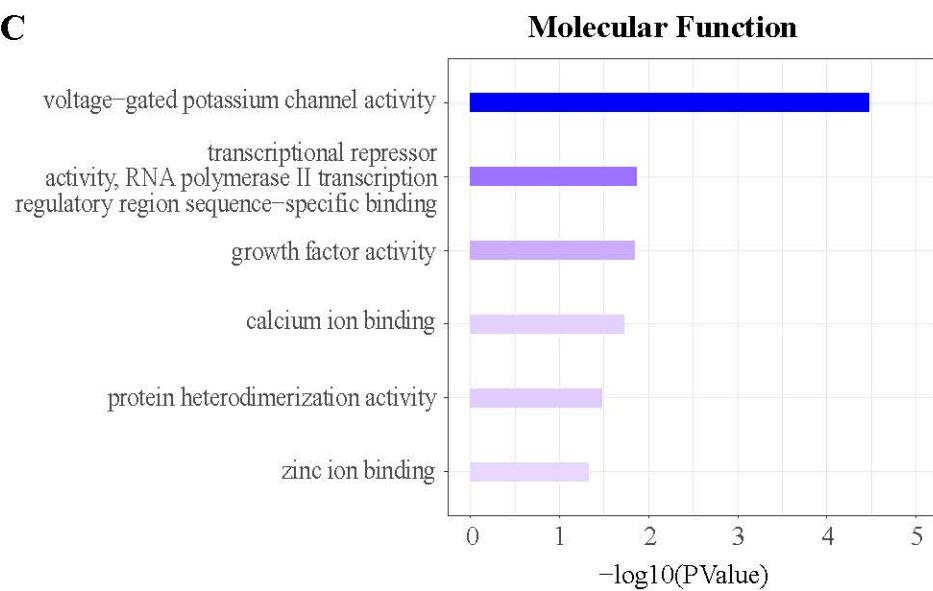

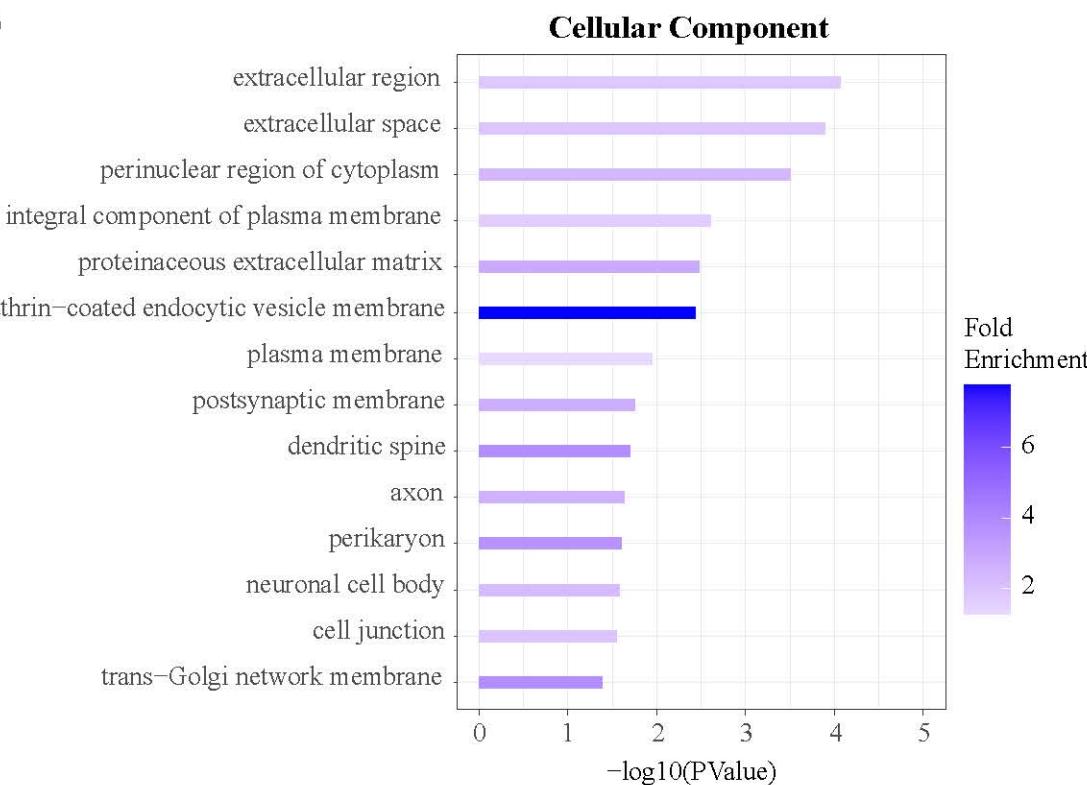

Artificial synapse formation assay. To address whether p.A53T- α Syn causes early synaptogenesis defects artificial synapse formation assays (ASFs) were employed as they represent a powerful tool to screen CAMs (Biederer and Scheiffele, 2007). ASFs are co-cultures of non-neuronal cells that present a post-synaptic adhesion neuronal protein on their plasma membrane, with neurons. These proteins are adequate to induce the formation of presynaptic specializatons (Biederer and Scheiffele, 2007). In the present study iPSC-

derived neurons were employed to investigate the synaptic connections between mutant neurons and HEK293T cells overexpressing two of the most well studied postsynaptic molecules, NLGN2 and NLGN4, which belong to the family of neuroligins, a class of four major cell adhesion molecules (Biederer and Scheiffele, 2007). Therefore no additional positive control plasmids were required for this study.

HEK293T (500K cells/well) were plated in 6-well plates and transfected with EGFP (control plasmid, pCMV-EGFP, InVitrogen), and hemagglutinin (HA) tagged NLGN2 (pCMV3-SP-NLNG2-HA, SINO Biological) and NLGN4 (Pcag-HA-NLGN4, Addgene) plasmids using calcium phosphate. Transfected HEK293T cells, were incubated at 37°C for 16-18 hours and cells with transfection efficiency of ~75-80% were dissociated and seeded at a density of 20k cells/well on neurons for 24 hours. Co-cultures were fixed with 4% PFA and stained for Synapsin1 and HA antibodies, to visualize the presynaptic induction of the selected postsynaptic molecules. Artificial contacts were captured by confocal imaging and analyzed by ImageJ software. To semi-automatically quantify the artificial synaptic potency of the two neuroligins, a pipeline based on the co-culture index (C.I.) measurement was used. Briefly, this approach counts the Synapsin1 density that is related to the target HEK293T cells, in a 2 μm radius ring inward and outward from the edge HEK293T, and excludes background Synapsin1 distribution, in a 4 μm radius ring 10 μm away from the HEK293T. HEK293T cells with $CI \geq 1$ are considered as positive cells and synaptic formation is measured (Jiang et al., 2017). Data was derived from n=2-3 independent culture systems.
