Table S12. Shoot values for *Triticum aestivum* seedlings (Shoot length, Fresh and Dry mass and Dry/Fresh mass ratio) planted in soil sampled at three locations (Mladost, Kajzerica and Nasip) with three samples on each site, inside the stand of the Bohemian knotweed, at the edge of the stand and controls outside the stand.

locality	position	length (cm)	mass fresh [g]	mass dry [g]	mass ratio dry/fresh

Lab protocol LP1. Kotzmann method for humus content determination.

Humus content was determined using the Kotzmann method, through the consumption of potassium permanganate (KMnO_4), a strong oxidant. 0.2 g of ground soil was mixed with 130 ml of distilled water in an Erlenmeyer flask with the addition of 20 ml 32% H_2SO_4 and 50 ml of 0.1 M KMnO_4 . The suspensions were cooked, boiling for 10 minutes, immediately after which the excess KMnO_4 was titrated using 0.1 M oxalic acid ($\text{H}_2\text{C}_2\text{O}_4$) until discoloration. Since the decolorization is very slow, the excess of added oxalic acid was retitrated with 0.1 M KMnO_4 solution. Humus content of the samples was calculated according to the following formulas:

$$\omega (\text{C}) = \frac{V (\text{g}/\text{cm}^3) * 0.000514 \text{ g}}{m (\text{g})} * 100$$

$$\omega (\text{humus}) = \omega (\text{C}) * 1.72$$

ω – mass fraction, V – volume of 0.1 M KMnO_4 spent for oxidation, 0.000514 g – mass of carbon that oxidizes 1 ml of 0.1 M KMnO_4 solution, m – mass of soil sample
